Dark Matter Clumps and Streams

From Numerical Simulations to Detection Efforts

Michael Kuhlen, UC Berkeley

Outline

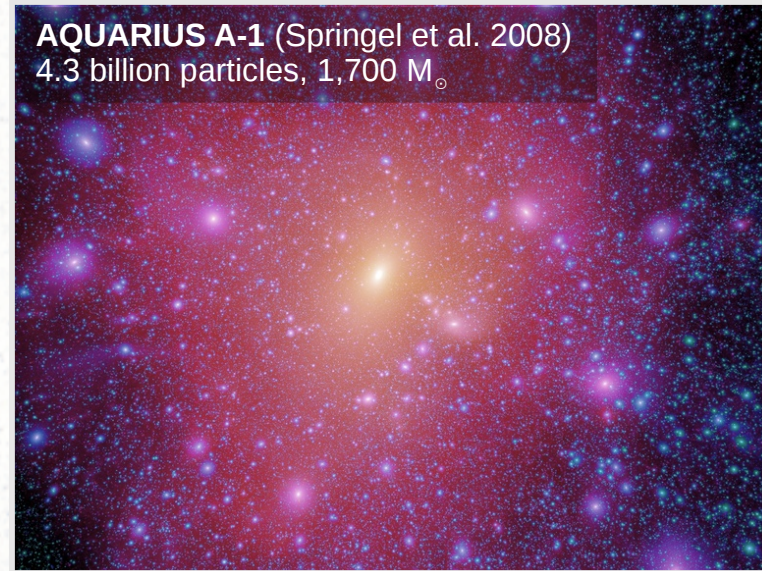

- Numerical Simulations State-of-the-Art
- Substructure: Astrophysics
- Substructure: Particle physics
 - As individual sources of DM annihilation: dwarf galaxies and dark subhalos
 - As a diffuse background from the cumulative annihilation in all Galactic subhalos
 - As an annihilation “boost factor”
 - As signatures in direct detection experiments
- Conclusions

I. Dark Matter Simulations: The State Of The Art

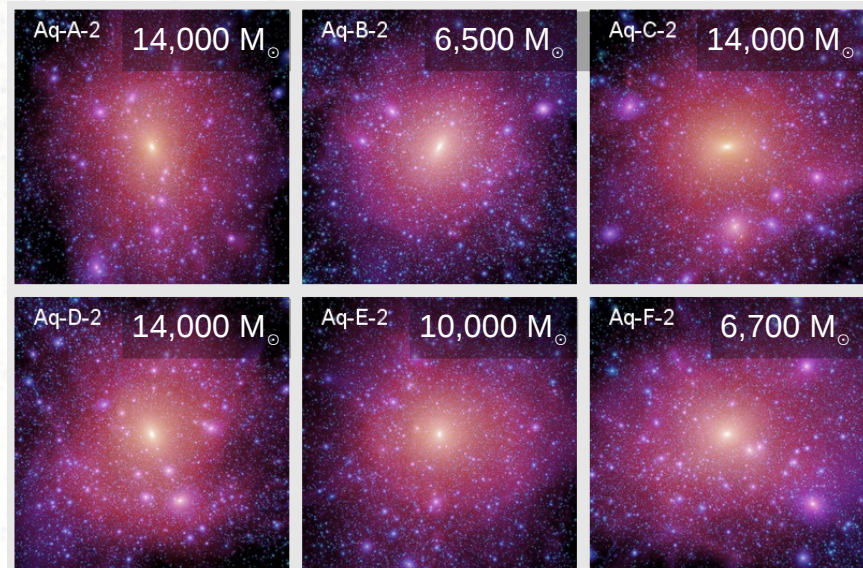

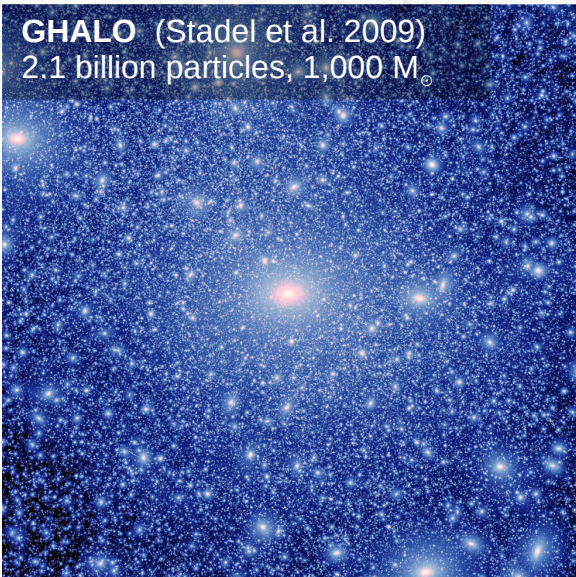

VIA LACTEA II (Diemand et al. 2008)
1.1 billion particles, 4,000 M_{\odot}

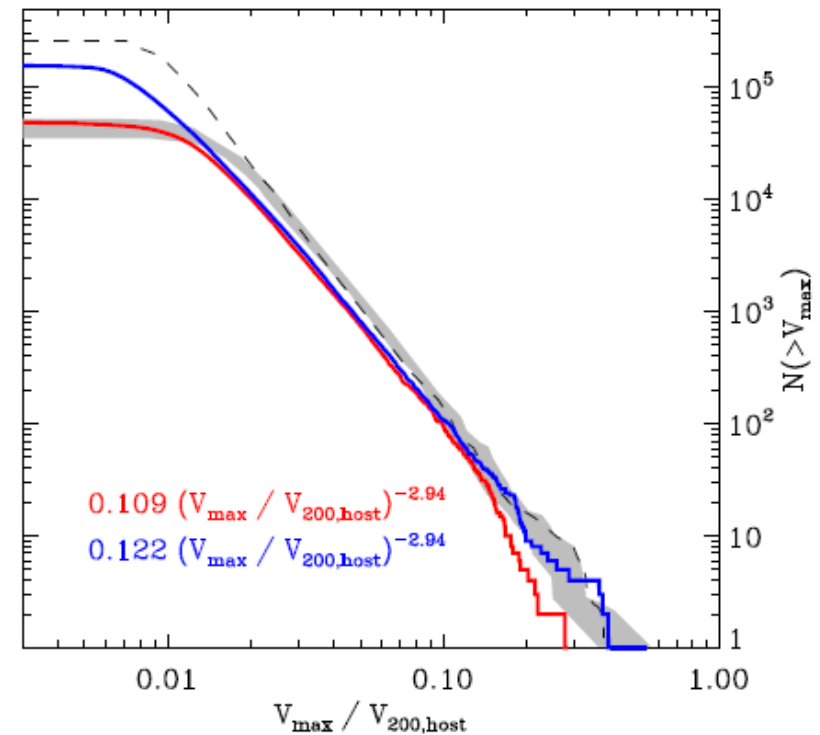

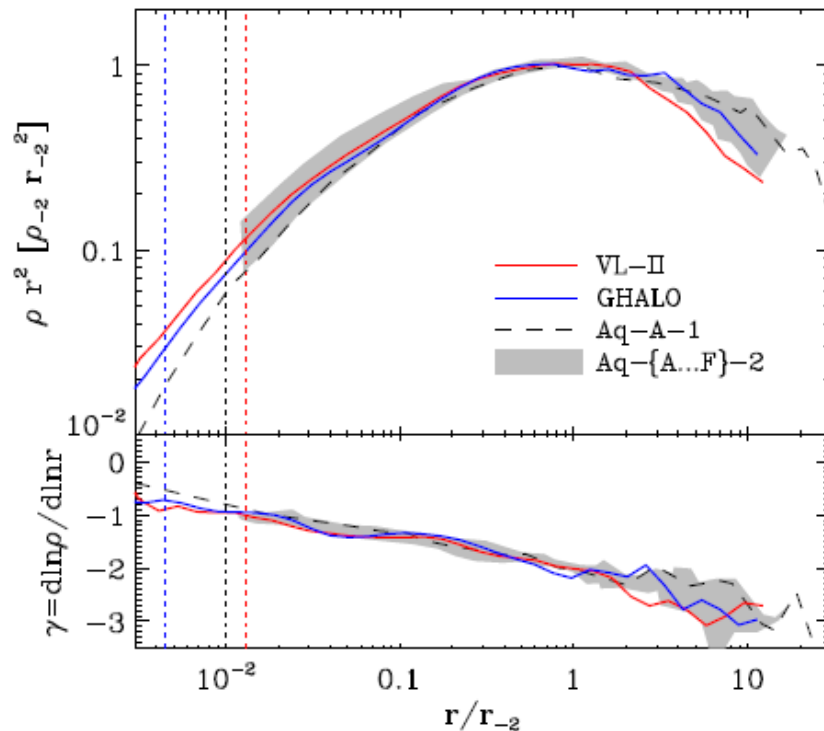

AQUARIUS A-1 (Springel et al. 2008)
4.3 billion particles, 1,700 M_{\odot}

GHALO (Stadel et al. 2009)
2.1 billion particles, 1,000 M_{\odot}

Via Lactea II/GHALO vs. Aquarius

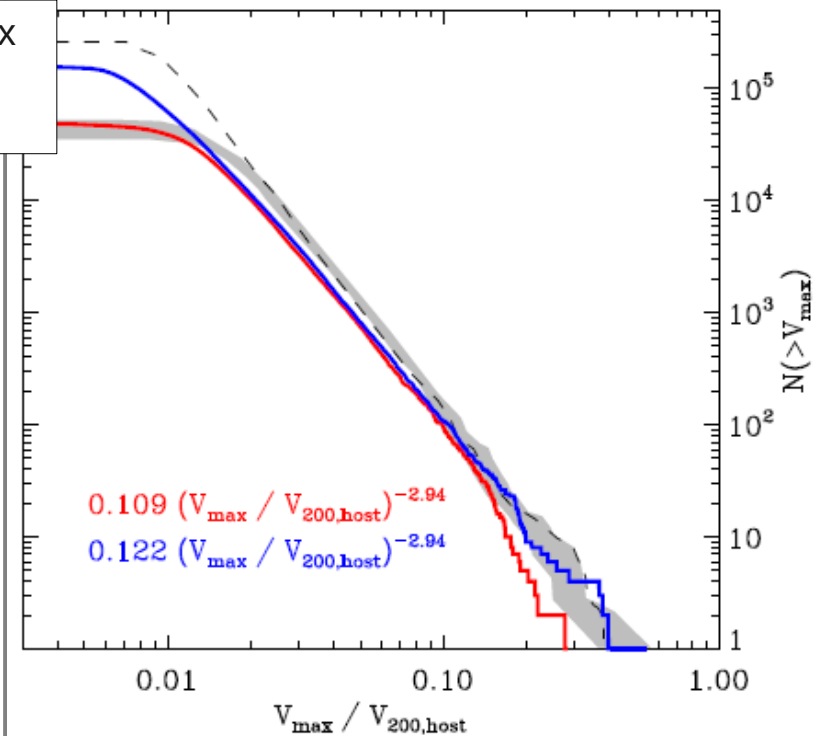

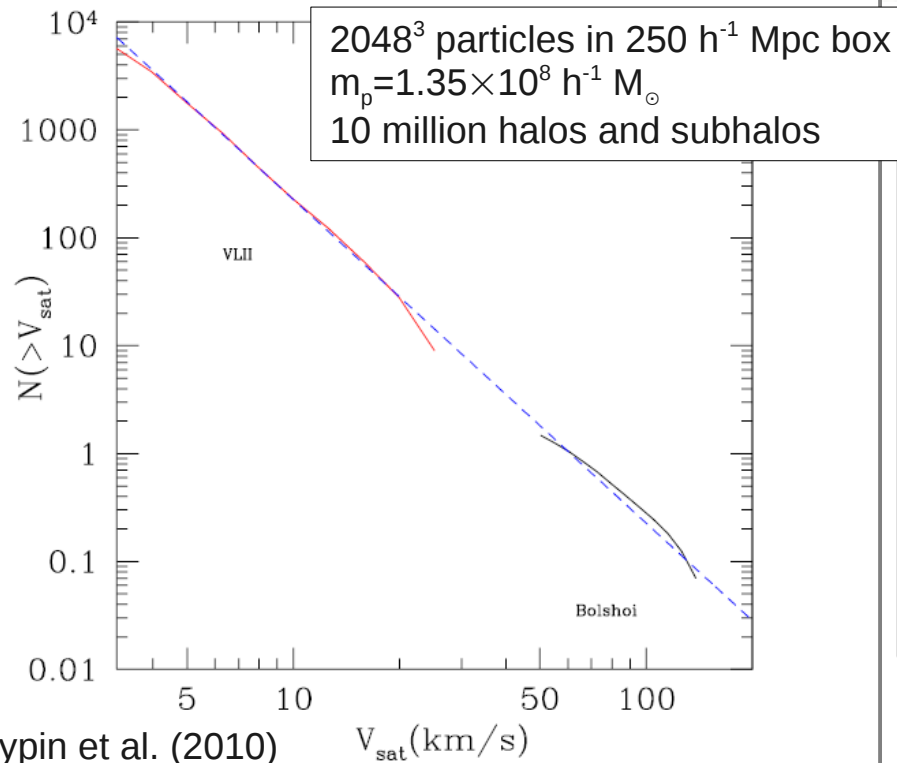

Via Lactea II, GHALO: **PKDGRAV2m**
Aquarius: **Gadget-3**

Once appropriately scaled,
VL-II, GHALO, and Aquarius
agree with each other.

Via Lactea II/GHALO vs. Aquarius

Comparison with Bolshoi simulation

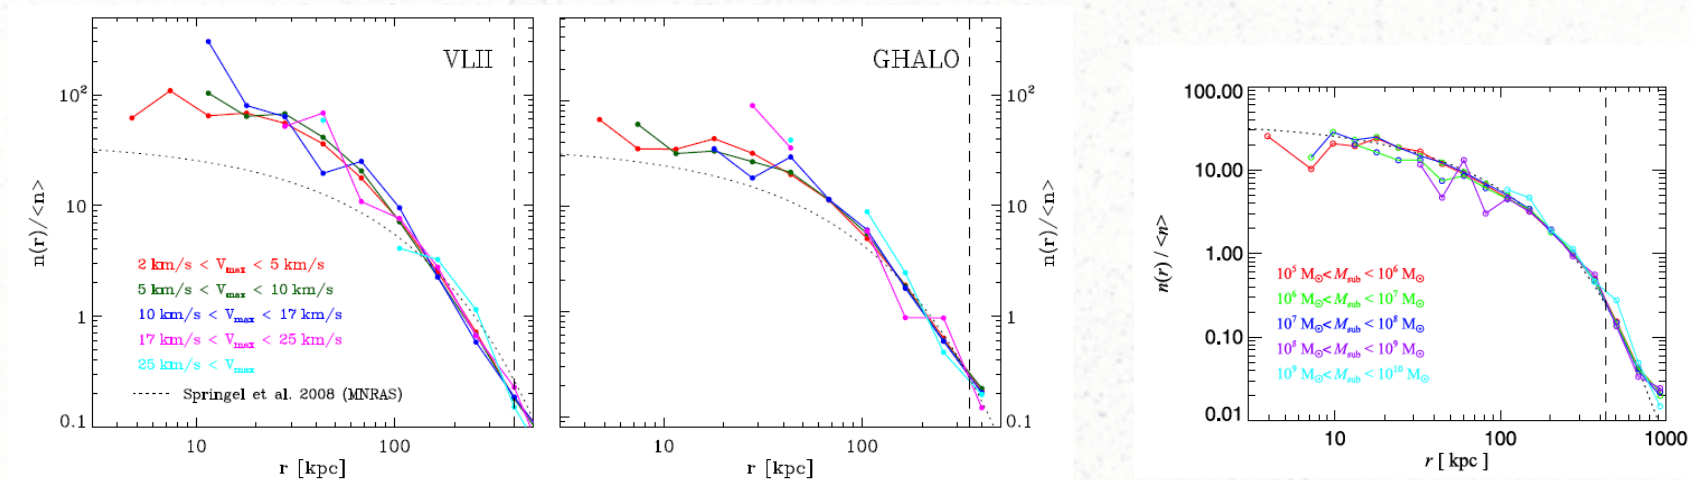

Via Lactea II, GHALO: **PKDGRAV2m**
Aquarius: **Gadget-3**

Once appropriately scaled,
VL-II, GHALO, and Aquarius
agree with each other.

Via Lactea II/GHALO vs. Aquarius

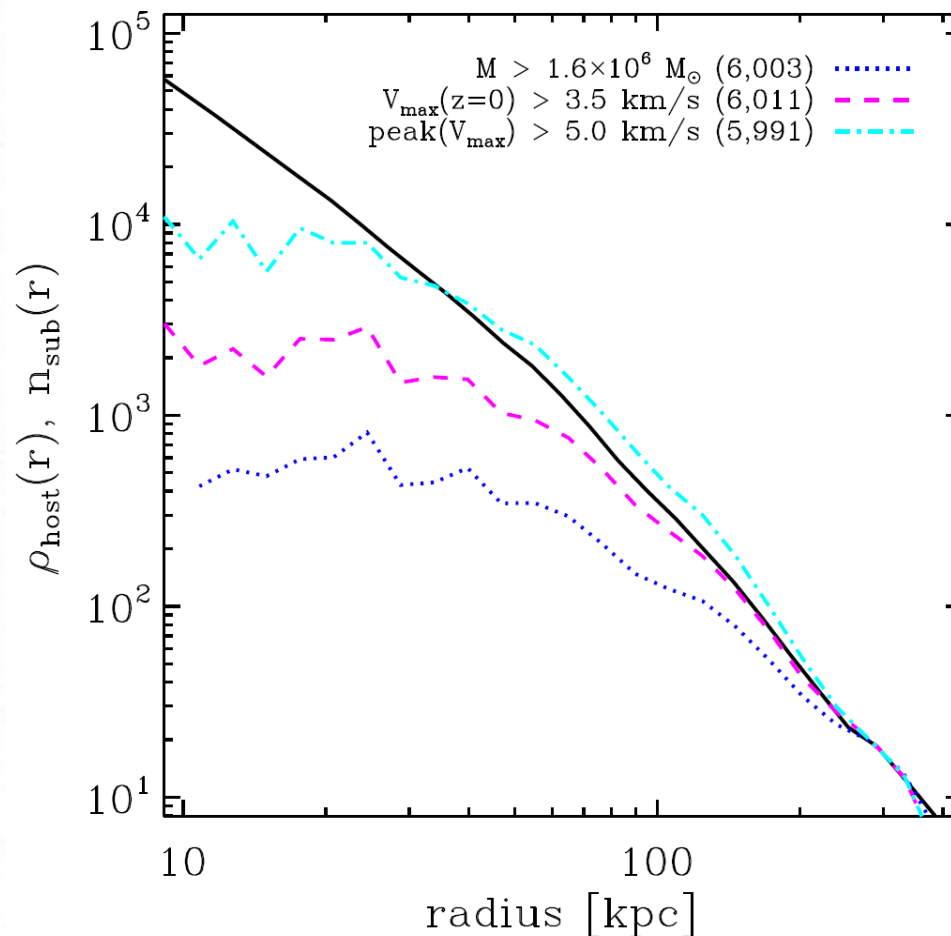

Some differences remain, e.g. in the radial distribution of subhalos.

Possible explanations:

- Slightly different cosmology? $\sigma_8=0.76$, $n_s=0.96$ in VL2/GHALO
 $\sigma_8=0.9$, $n_s=1$ in Aquarius
- Different subhalo finders? 6DFOF vs. SUBFIND
- Different sample selection? V_{\max} vs. M

The Radial Distribution of Subhalos Depends on Selection

The subhalo radial distribution is **anti-biased** with respect to the DM density: fewer subhalos in the center.

(cf. Ghigna et al. 2000; de Lucia et al. 2004)

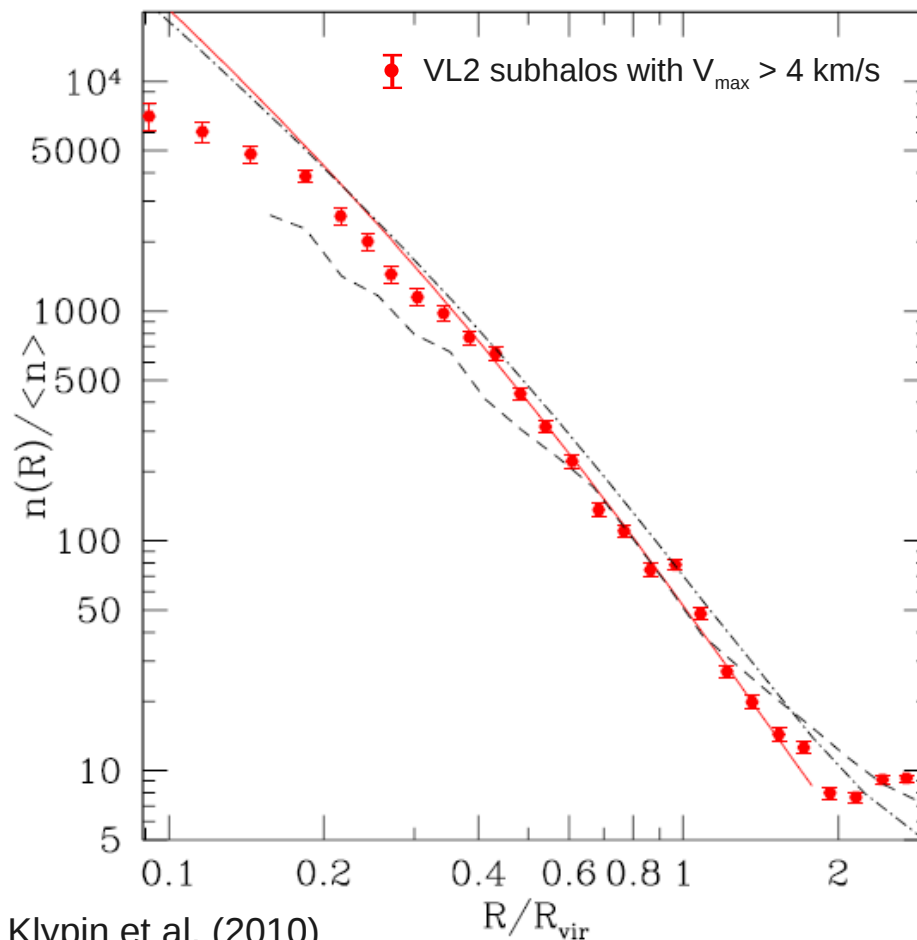

Depends on how one selection:

- strongest for $M(z=0)$ -selected,
- weaker for $V_{\text{max}}(z=0)$ -selected,
- disappears down to ~ 30 kpc for $\text{peak}(V_{\text{max}})$ -selected.

(cf. Nagai & Kravtsov 2005; Faltenbacher & Diemand 2006)

The Radial Distribution of Subhalos Depends on Selection

Subhalo $n(R)$ normalized with Bolshoi.

The subhalo radial distribution is **anti-biased** with respect to the DM density: fewer subhalos in the center.

(cf. Ghigna et al. 2000; de Lucia et al. 2004)

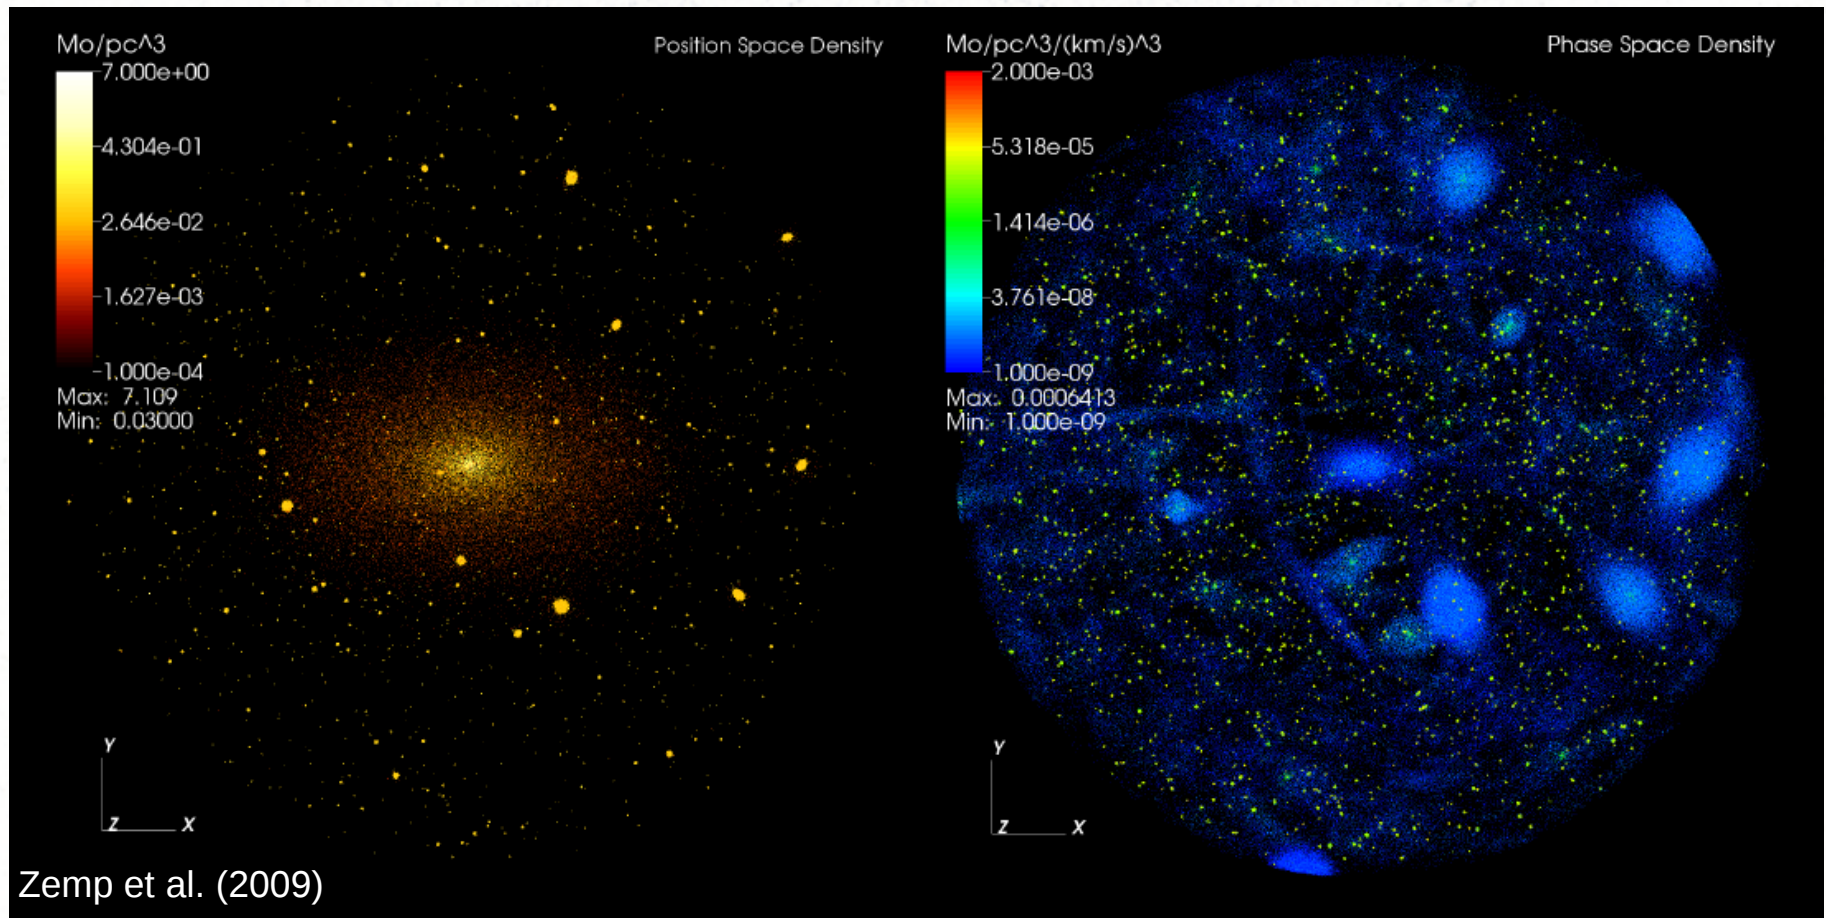

Depends on how one selection:

- strongest for $M(z=0)$ -selected,
- weaker for $V_{\max}(z=0)$ -selected,
- disappears down to ~ 30 kpc for peak(V_{\max})-selected.

(cf. Nagai & Kravtsov 2005; Faltenbacher & Diemand 2006)

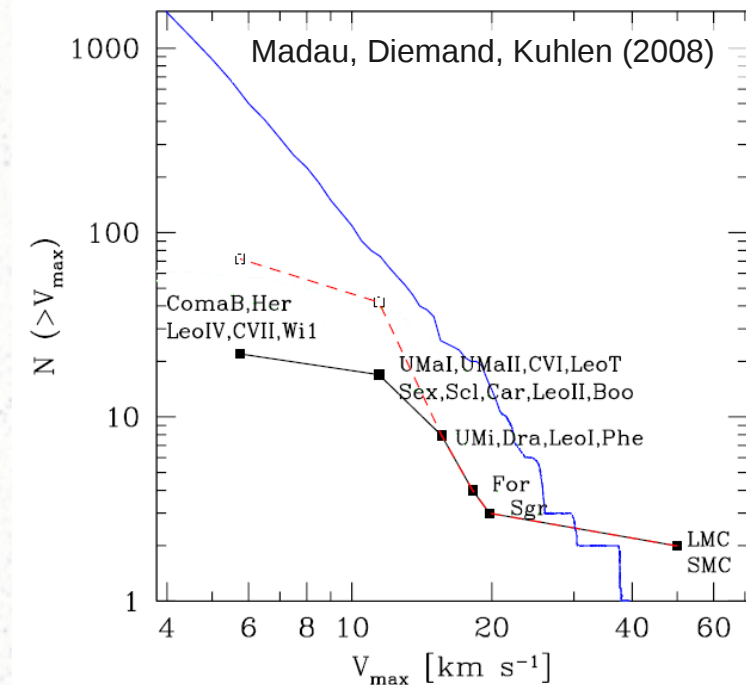

Velocity Space Substructure

Whereas previous simulations were almost completely smooth in the central region, with VL-II we resolve lots of subhalos and tidal streams even down to 8 kpc.

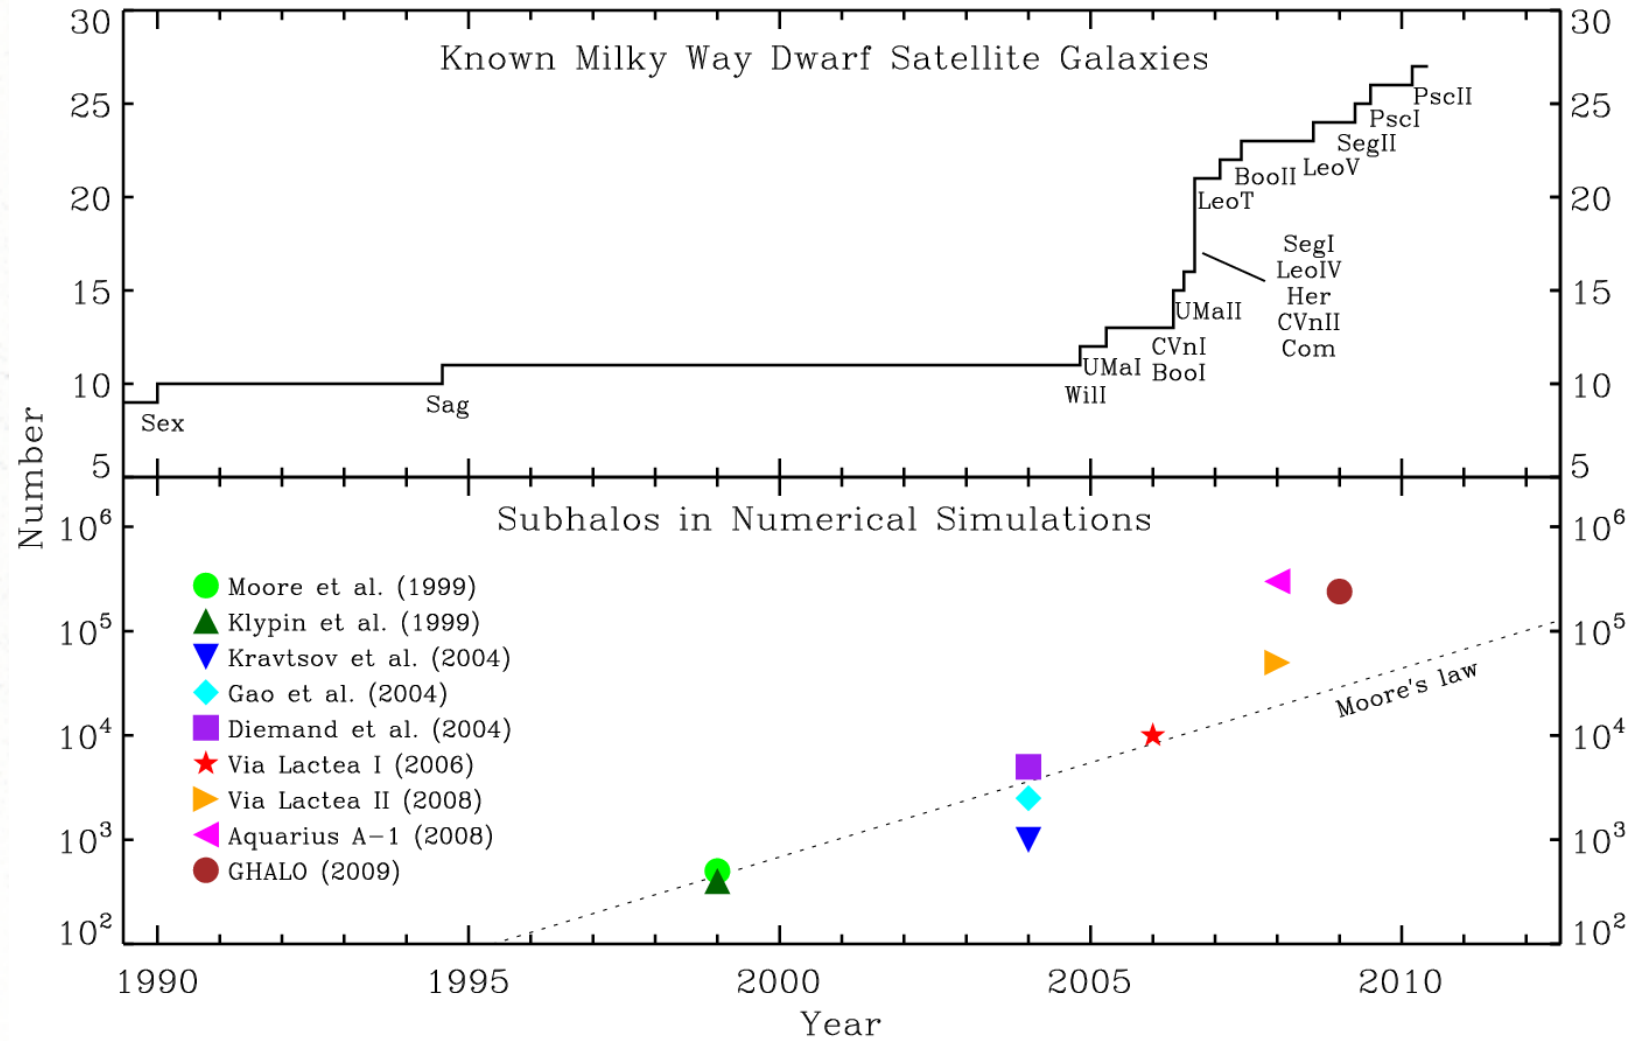

Dark Matter Substructure: Astrophysics

- **Hosts for Dwarf Galaxies**
 - The Missing Satellites Problem
 - How well do stellar radial velocities constrain the halo mass and the central phase space density?
 - What does this tell us about the nature of DM?
- Galactic disk bombardment
 - Heating, warps
 - Non-axisymmetric spiral structure in HI?
- Effect on cold stellar tidal streams
 - gaps, kinks?
- Effect on strong gravitational lensing:
 - Flux ratio anomalies
 - Time delay perturbations

Kochanek & Dalal (2004)

Dark Matter Substructure: Particle Physics

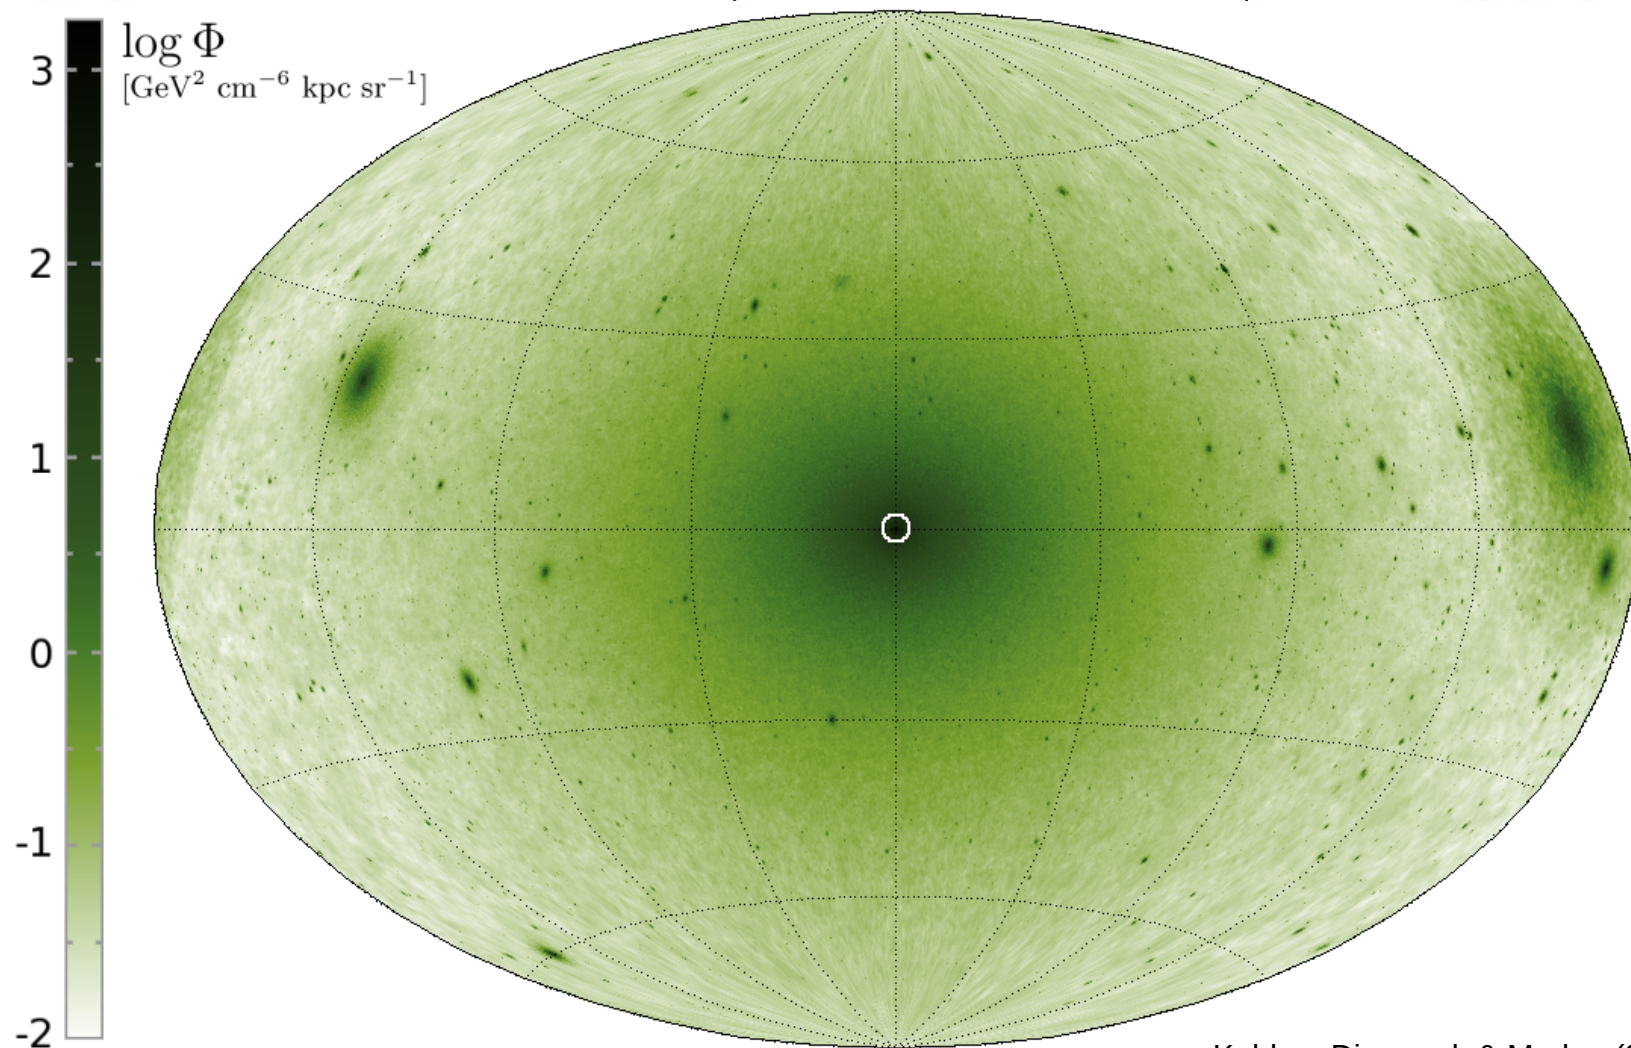

- 1) Subhalos as individual DM annihilation sources
 - a) Luminous dwarf satellite galaxies
 - b) Dark subhalos
- 2) Cumulative signal from all Galactic subhalos
- 3) Substructure “boost factor”
- 4) Velocity substructure and Direct Detection

DM annihilation and its signals

1) Subhalos as individual DM annihilation sources

$$N_\gamma = \left[\int_{\text{line of sight}} \rho_{\text{DM}}^2 dl(\psi) \right] \frac{\langle \sigma v \rangle}{2M_\chi^2} \left[\int_{E_{th}}^{M_\chi} \left(\frac{dN_\gamma}{dE} \right) A_{\text{eff}}(E) dE \right] \frac{\Delta\Omega}{4\pi} \tau_{\text{exp}}$$

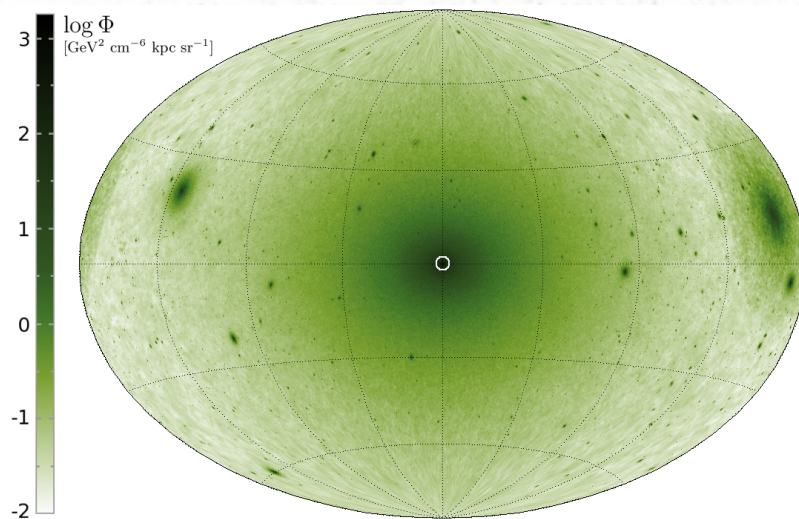

1) Subhalos as individual DM annihilation sources

$$N_\gamma = \left[\int_{\text{line of sight}} \rho_{\text{DM}}^2 dl(\psi) \right] \frac{\langle \sigma v \rangle}{2M_\chi^2} \left[\int_{E_{th}}^{M_\chi} \left(\frac{dN_\gamma}{dE} \right) A_{\text{eff}}(E) dE \right] \frac{\Delta\Omega}{4\pi} \tau_{\text{exp}}$$

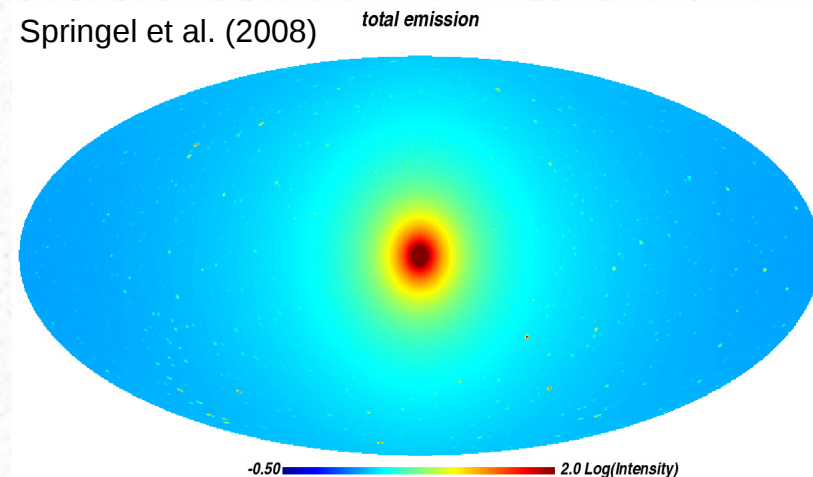

Huh? How come these look so different?

Via Lactea II

Kuhlen, Diemand, & Madau (2008)

Aquarius

“For simplicity and for better visual representation they [the subhalos] have been represented as point sources that were smoothed with a Gaussian beam of 40 arcmin.”

1) Subhalos as individual DM annihilation sources

Fermi/LAT *GTOBSSIM* Monte-Carlo Simulation (with Brandon Anderson & Robert Johnson, SCIPP)

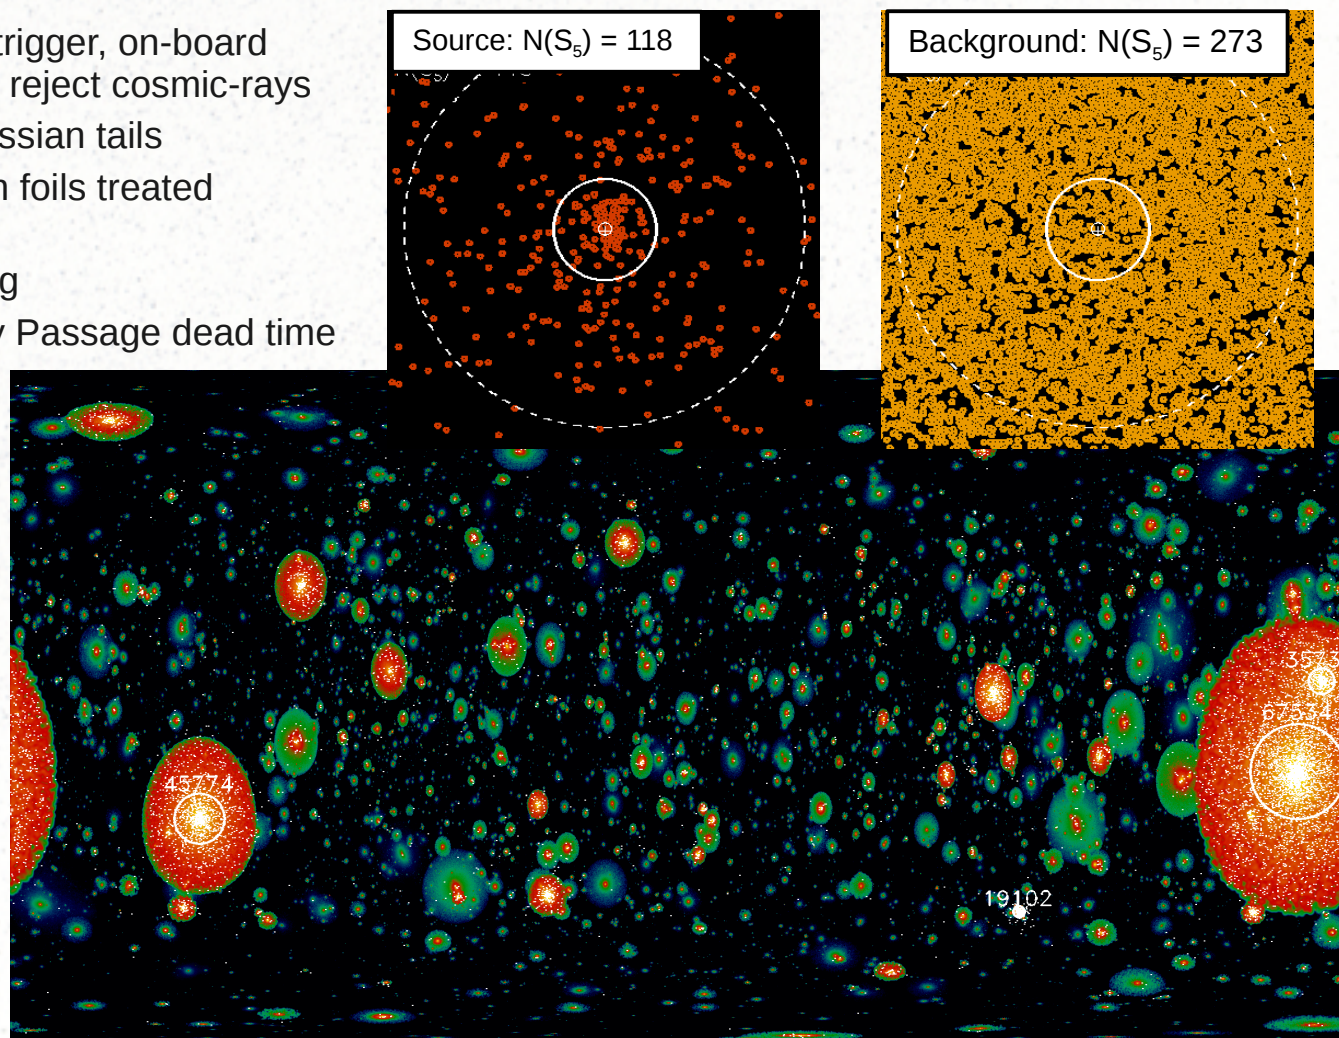

- LAT A_{eff} dependence on viewing angle and photon energy
- Selection effects: LAT trigger, on-board filter, offline analysis to reject cosmic-rays
- PSF includes non-Gaussian tails
- Thin and thick tungsten foils treated separately
- $\pm 35^\circ$ instrument rocking
- South Atlantic Anomaly Passage dead time

Energy-dependent
ROI optimization

Calculate detection
significance:

$$P = \sum_{i=k}^{\infty} \frac{\lambda^k e^{-\lambda}}{k!}$$

$$S = \sqrt{2} \operatorname{erf}^{-1}(1 - 2P)$$

1) Subhalos as individual DM annihilation sources

$$S = \sqrt{2} \operatorname{erf}^{-1}(1 - 2P)$$

1) Subhalos as individual DM annihilation sources

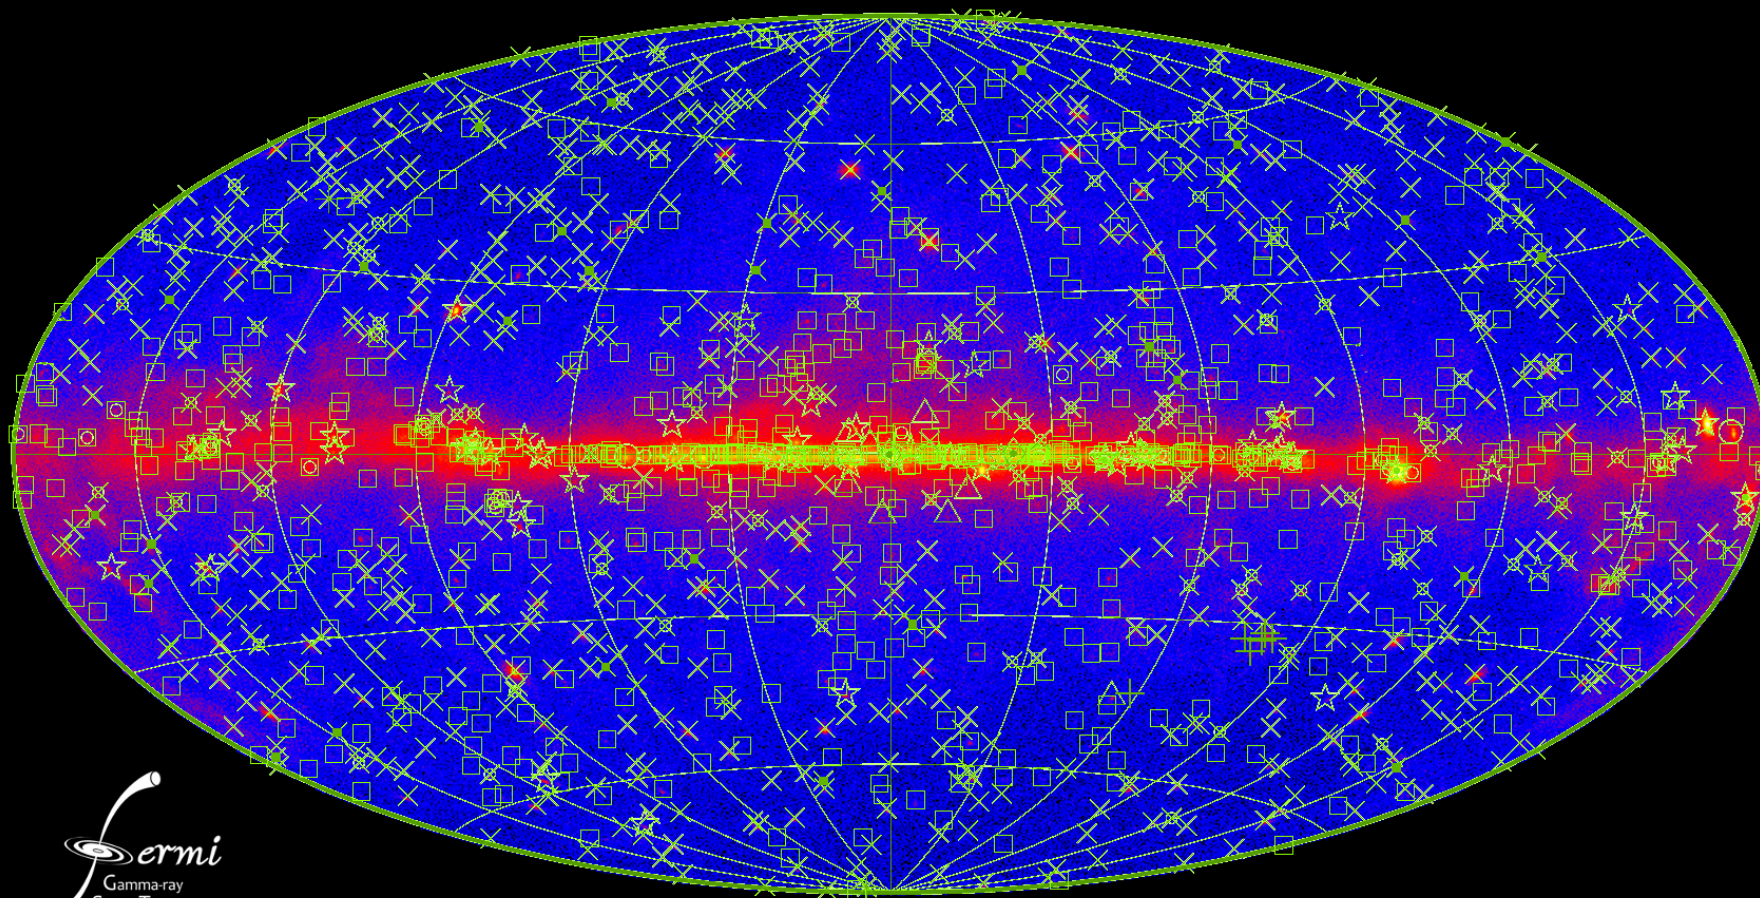

Fermi was launched on June 11th 2008 and has been observing the sky for more than 2 years.

1) Subhalos as individual DM annihilation sources

So far, now dark matter signal has been detected. ☹

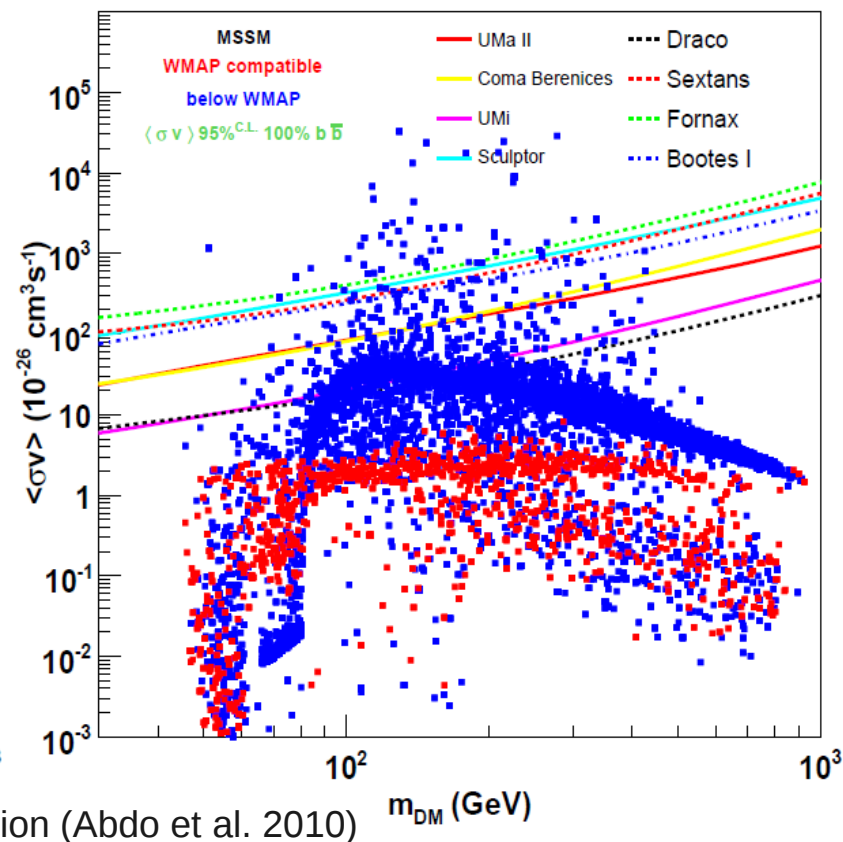

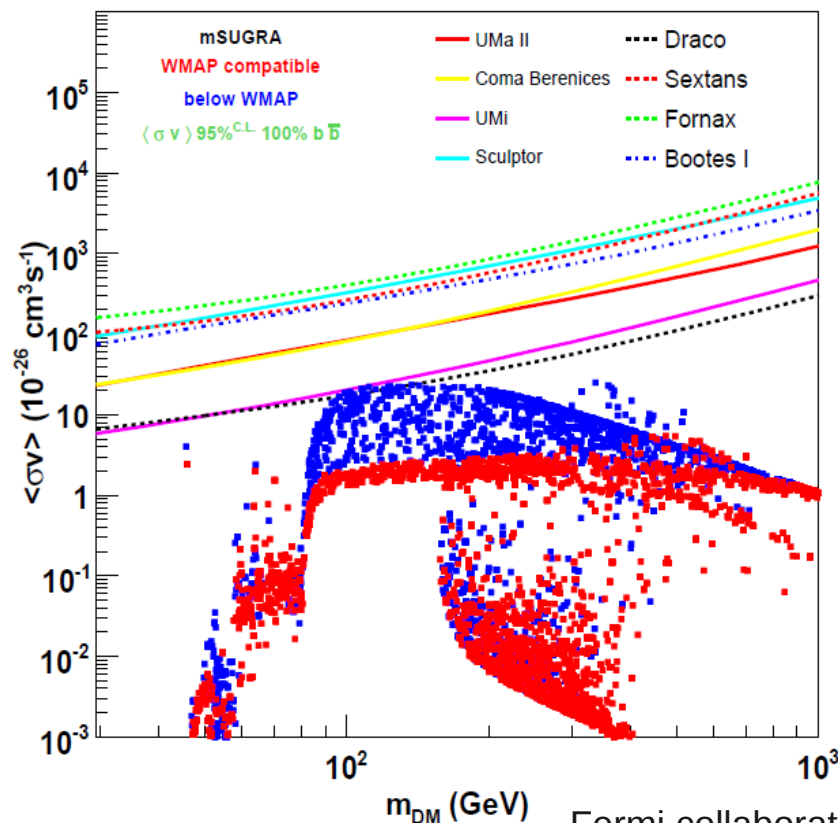

□ No association		□ Possible association with nearby SNR or PWN	
× AGN – blazar	* Starburst Gal	☆ Pulsar	☆ Pulsar w/PWN
× AGN – unknown	+ Galaxy	◇ PWN	△ Globular cluster
× AGN – non blazar		○ SNR	⊠ XRB or MQO

1) Subhalos as individual DM annihilation sources

Luminous dwarf satellite galaxies

- Know where to look
- Can stack data
- Targeted observations with ACTs
- Distance known \rightarrow better constraints

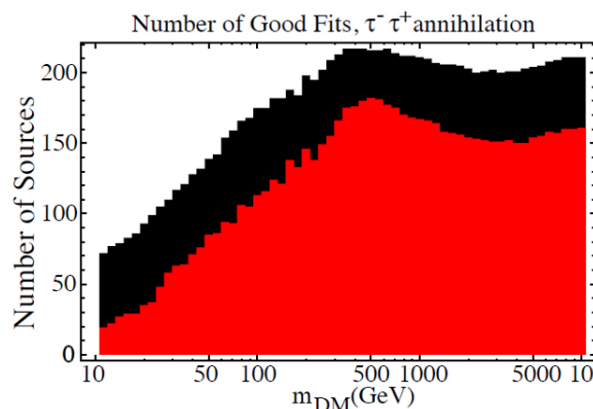

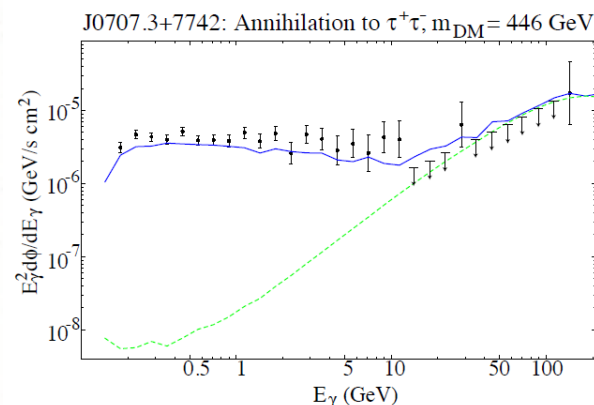

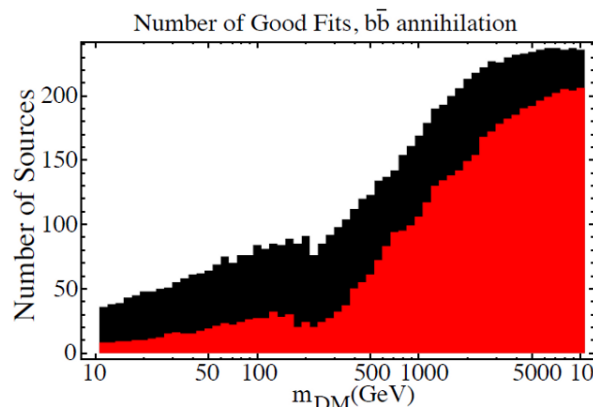

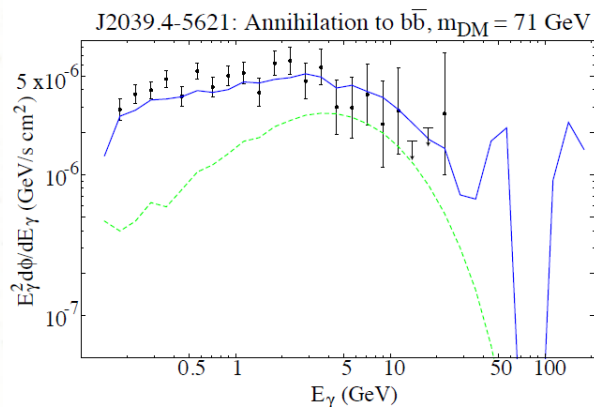

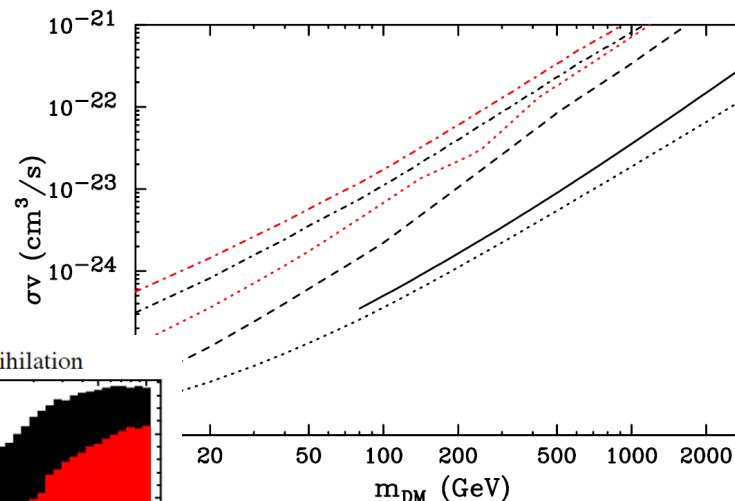

Fermi collaboration (Abdo et al. 2010)

1) Subhalos as individual DM annihilation sources

Dark Subhalos

- Need a large area survey
- Could in principle be very nearby
- Less confusion from astrophysical sources

Buckley & Hooper (2010)

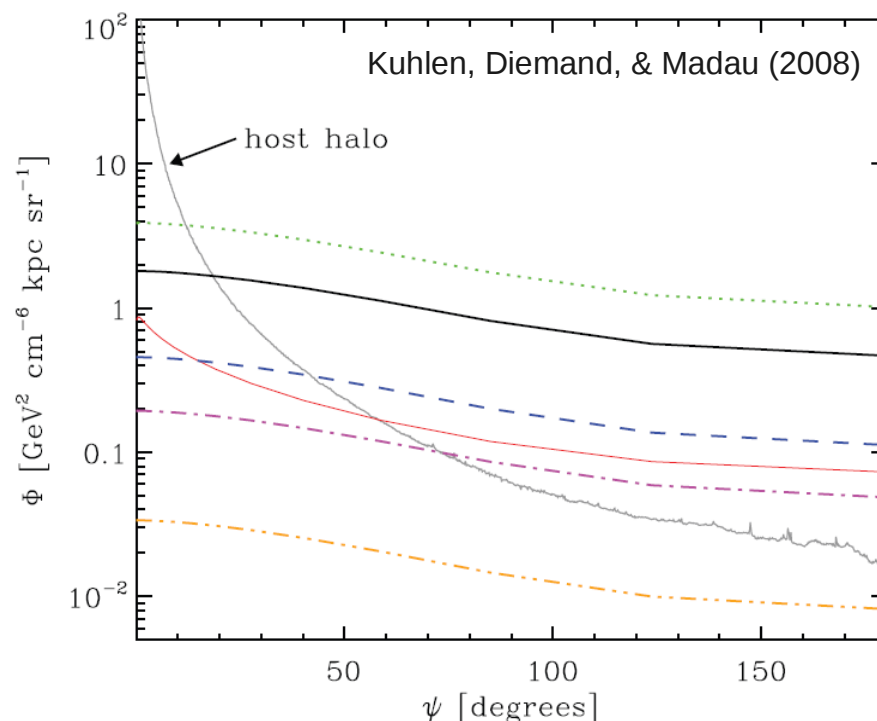

- Searched FGST point source catalog
- No definite detections
- Limits competitive with those from dwarf galaxies
- ~30 subhalos could be hiding as point sources

2) Cumulative signal from all Galactic subhalos

SUBHALO MASS FUNCTION MODELS

α	m_0 (M_\odot)	N_{tot}	M_{tot} (M_\odot)	f_{tot}	M_u (M_\odot)	f_u
2.0.....	10^{-6}	2.5×10^{16}	9.3×10^{11}	0.53	7.0×10^{11}	0.40
1.9.....	10^{-6}	9.2×10^{14}	3.2×10^{11}	0.19	1.2×10^{11}	0.070
1.8.....	10^{-6}	3.3×10^{13}	2.1×10^{11}	0.12	3.3×10^{10}	0.018
2.0.....	1	2.5×10^{10}	5.8×10^{11}	0.33	3.5×10^{11}	0.20
2.0.....	10^{-12}	2.5×10^{22}	1.3×10^{12}	0.73	1.0×10^{12}	0.60

- CDM predicts an enormous number of low mass subhalos.
- Their cumulative annihilation signal should result in a diffuse flux.
- Less centrally concentrated than the host halo flux.
- Reduced contrast between center and anti-center. Bad news for IceCube? (Rott et al. 2010)
- Angular fluctuations are an interesting signal to be searched for (Siegal-Gaskins et al. 2008, Ando 2009)

3) Substructure “Boost Factor”

The term “Boost Factor” has been used (abused?) in many ways:

- Enhancement in total halo luminosity from NFW profile compared to a spherical tophat.
- Enhancement in total halo luminosity from substructure (and sub-substructure, etc.) compared to a smooth NFW density profile.
- Enhancement of local (8kpc) annihilation rate over $(0.3 \text{ GeV cm}^{-3})^2$.
- Enhancement of Galactic Center annihilation rate.
- Enhancement of the surface brightness of angularly resolved subhalos.

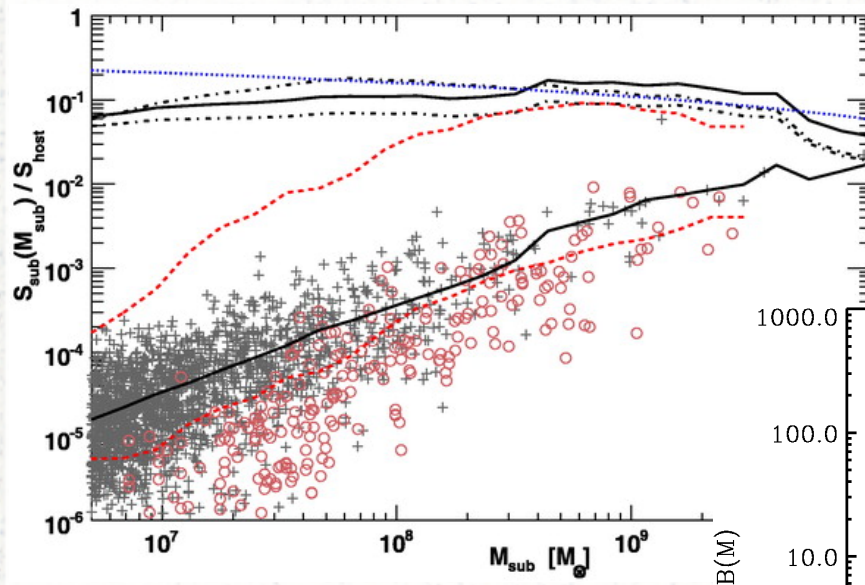

There is no one single “Boost Factor”!

The enhancement due to clumpy substructure depends on source location and/or its angular extent.

3) Substructure “Boost Factor”

Total Halo Luminosity Boost Factor

- Only applicable to unresolved sources!
- Important for the extragalactic gamma-ray background

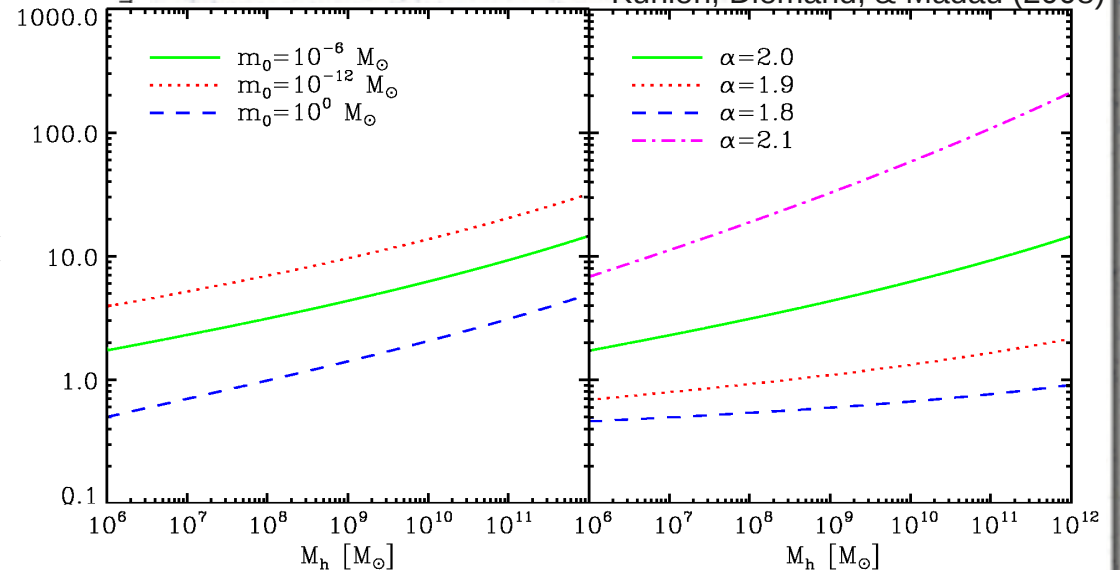

Diemand, Kuhlen, & Madau (2006) [VL-I]

$$\mathcal{L}(M) = [1 + B(M, m_0)] \tilde{\mathcal{L}}(M)$$

$$B(M) = \frac{A}{\tilde{\mathcal{L}}(M)} \int_{\ln m_0}^{\ln m_1} \left(\frac{m}{M}\right)^{1-\alpha} [1 + B(m)] \tilde{\mathcal{L}}(m) d\ln m.$$

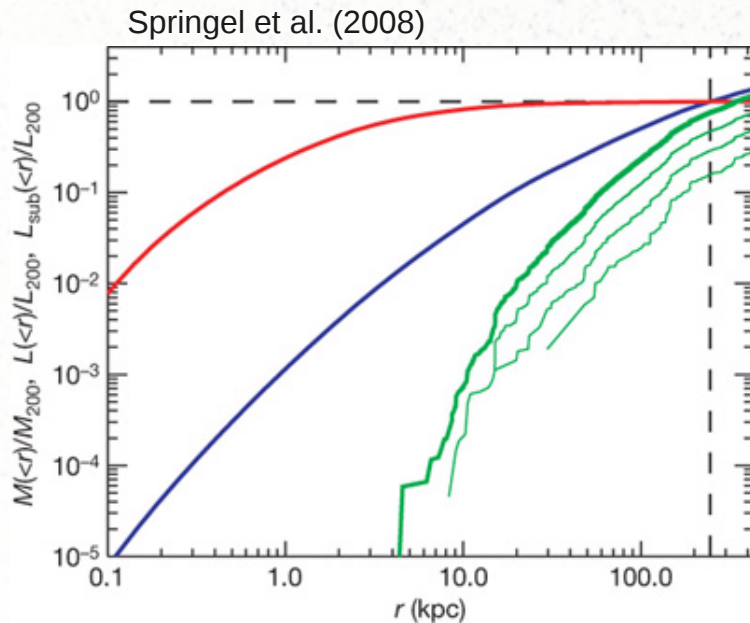

Kuhlen, Diemand, & Madau (2008)

3) Substructure “Boost Factor”

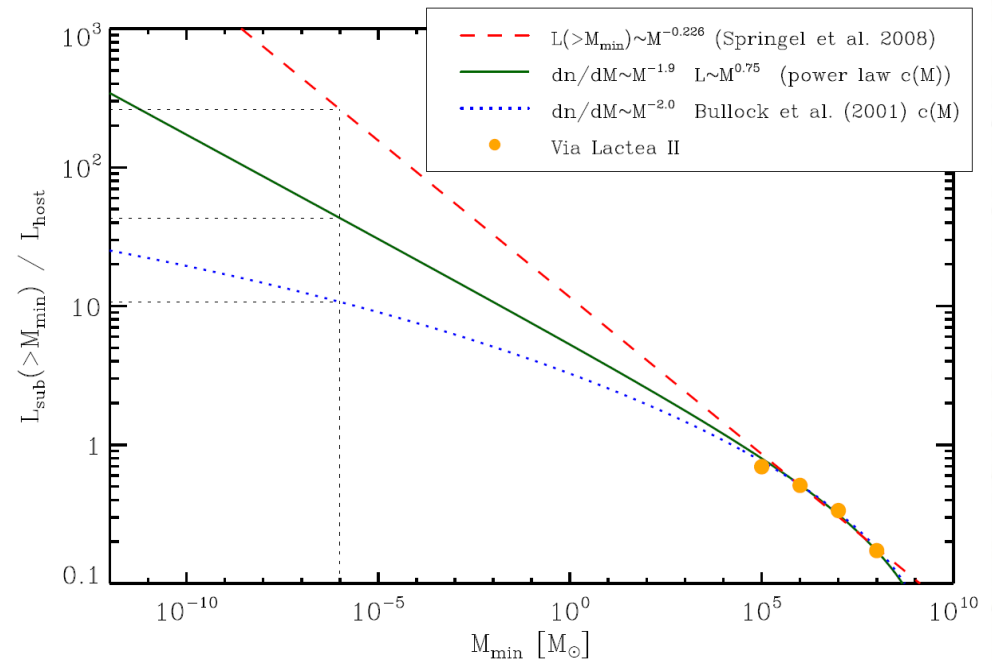

Total Halo Luminosity Boost Factor

- Only applicable to unresolved sources!
- Important for the extragalactic gamma-ray background.

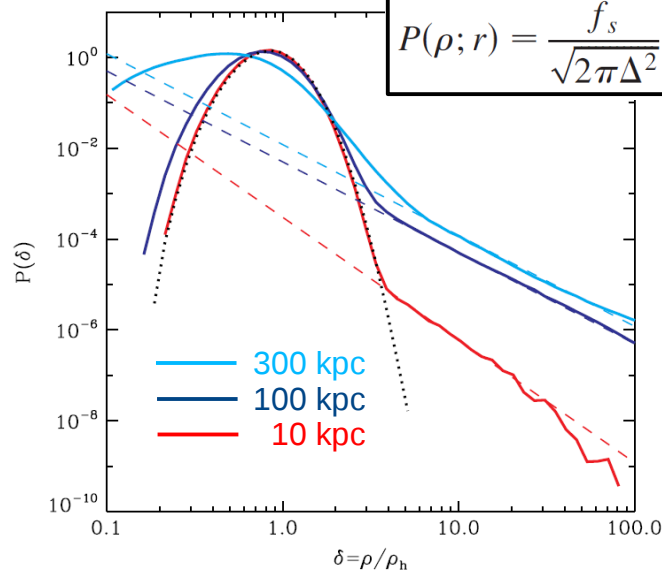

$$L(>M_{\min}) \sim M_{\min}^{-0.226}$$

Total boost factor for $M_{\min}=10^{-6} M_{\odot} = 232!$

Depends **critically** on what one assumes for the concentration-mass relation for subhalos below the simulations' resolution limit!

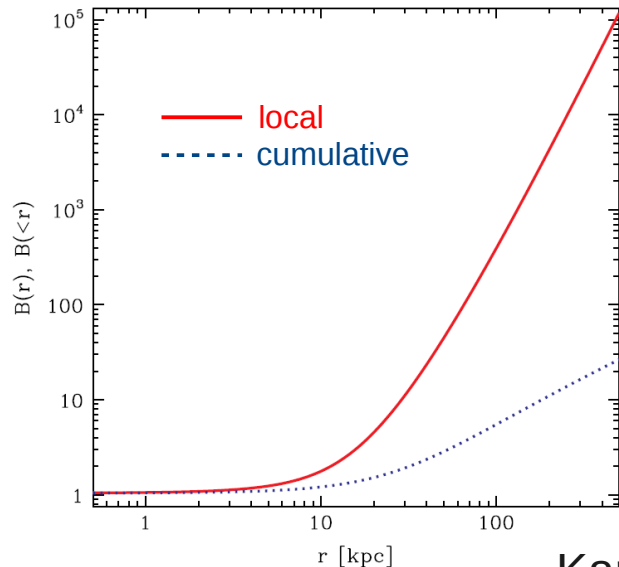

3) Substructure “Boost Factor”

$$P(\rho; r) = \frac{f_s}{\sqrt{2\pi}\Delta^2} \frac{1}{\rho} \exp\left\{-\frac{1}{2\Delta^2} \left[\ln\left(\frac{\rho}{\rho_h} e^{\Delta^2/2}\right)\right]^2\right\} + (1 - f_s) \frac{1 + \alpha(r)}{\rho_h} \Theta(\rho - \rho_h) \left(\frac{\rho}{\rho_h}\right)^{-(2+\alpha)}$$

- We measure the PDF of ρ/ρ_{host} in the simulation.
- It's fit well by a **log-normal** plus a **powerlaw** tail due to substructure.

$$\alpha \approx 0.0 \pm 0.1 \quad 1 - f_s(r) = 7 \times 10^{-3} \left(\frac{\bar{\rho}(r)}{\bar{\rho}(r = 100 \text{ kpc})} \right)^{-0.26}$$

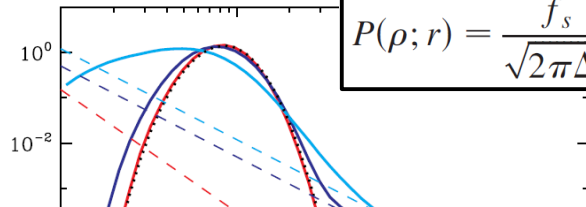

$$B(r) = \frac{\int \rho^2 dV}{\int [\bar{\rho}(r)]^2 dV} = \int_0^{\rho_{\text{max}}} P(\rho, r) \frac{\rho^2}{[\bar{\rho}(r)]^2} d\rho$$

$$B(r) = f_s e^{\Delta^2} + (1 - f_s) \frac{1 + \alpha}{1 - \alpha} \left[\left(\frac{\rho_{\text{max}}}{\rho_h} \right)^{1-\alpha} - 1 \right]$$

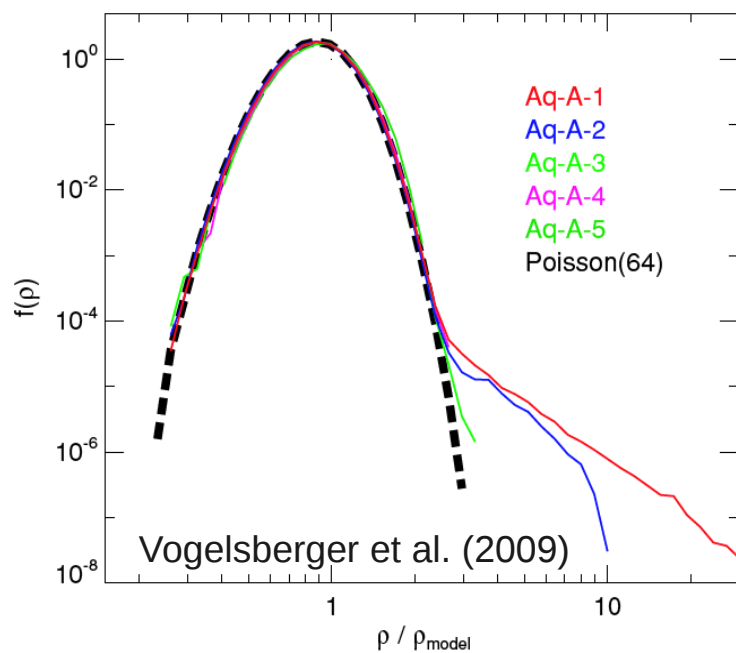

Local boost (e.g. at 8 kpc or at the G.C.) \neq Total boost

Kamionkowski, Koushiappas & Kuhlen (2010)

3) Substructure “Boost Factor”

$$P(\rho; r) = \frac{f_s}{\sqrt{2\pi}\Delta^2} \frac{1}{\rho} \exp\left\{-\frac{1}{2\Delta^2} \left[\ln\left(\frac{\rho}{\rho_h} e^{\Delta^2/2}\right)\right]^2\right\} + (1 - f_s) \frac{1 + \alpha(r)}{\rho_h} \Theta(\rho - \rho_h) \left(\frac{\rho}{\rho_h}\right)^{-(2+\alpha)}$$

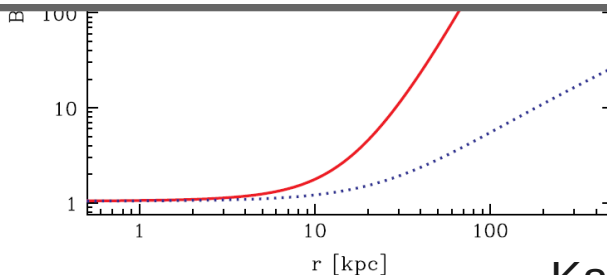

We measure the PDF of ρ/ρ_{host} in the simulation.

It fits well by a **log-normal** plus a **powerlaw** tail due to substructure.

$$\alpha \approx 0.0 \pm 0.1 \quad 1 - f_s(r) = 7 \times 10^{-3} \left(\frac{\bar{\rho}(r)}{\bar{\rho}(r = 100 \text{ kpc})} \right)^{-0.26}$$

$$B(r) = \frac{\int \rho^2 dV}{\int [\bar{\rho}(r)]^2 dV} = \int_0^{\rho_{\text{max}}} P(\rho, r) \frac{\rho^2}{[\bar{\rho}(r)]^2} d\rho$$

$$B(r) = f_s e^{\Delta^2} + (1 - f_s) \frac{1 + \alpha}{1 - \alpha} \left[\left(\frac{\rho_{\text{max}}}{\rho_h} \right)^{1-\alpha} - 1 \right]$$

Local boost (e.g. at 8 kpc or at the G.C.) \neq Total boost

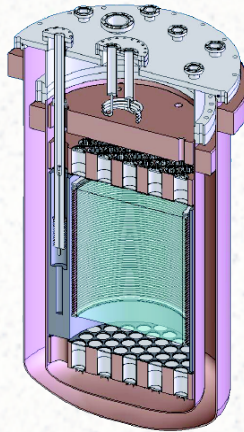

Kamionkowski, Koushiappas & Kuhlen (2010)

4) Substructure And Direct Detection

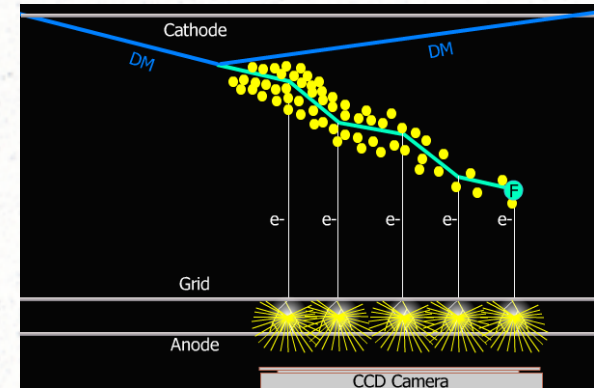

Cryogenic phonon detection
(e.g. CDMS)

Liquid Xenon scintillation
detectors (e.g. Xenon100, LUX)

Directionally sensitive
(e.g. DRIFT, DMTPC)

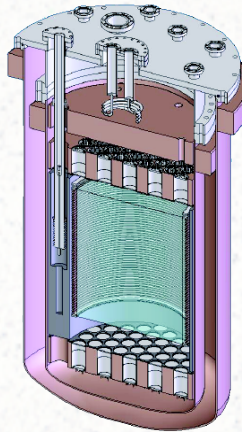

$$\frac{dR}{dE_R} = N_T M_N \frac{\rho_\chi \sigma_n}{2m_\chi \mu_{ne}^2} \frac{(f_p Z + f_n (A - Z))^2}{f_n^2} F^2[E_R] \int_{\beta_{min}}^{\infty} \frac{f(v)}{v} dv$$

4) Substructure And Direct Detection

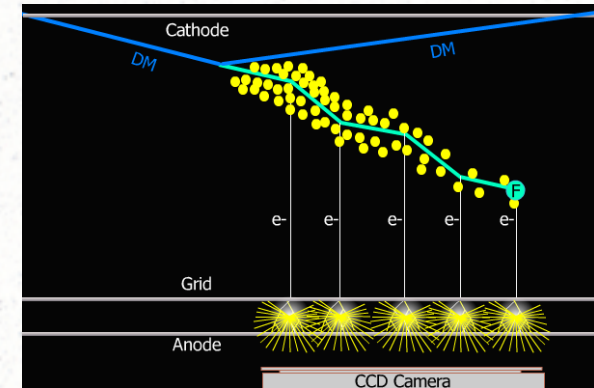

Cryogenic phonon detection
(e.g. CDMS)

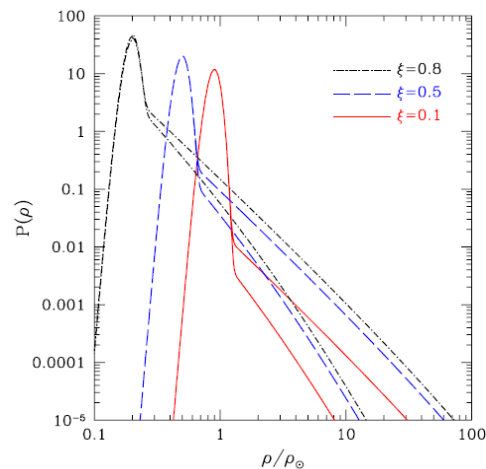

Liquid Xenon scintillation
detectors (e.g. Xenon100, LUX)

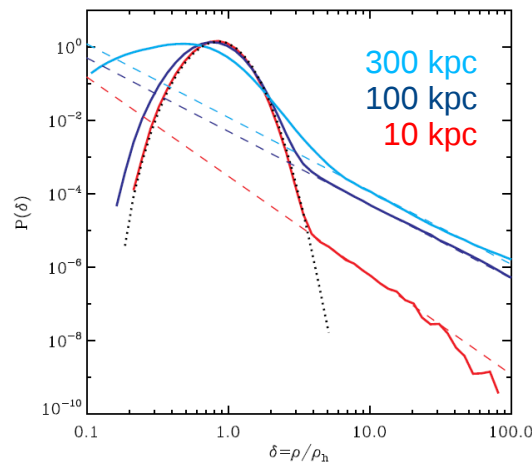

Directionally sensitive
(e.g. DRIFT, DMTPC)

$$\frac{dR}{dE_R} = N_T M_N \frac{\rho_\chi \sigma_n}{2m_\chi \mu_{ne}^2} \frac{(f_p Z + f_n (A - Z))^2}{f_n^2} F^2[E_R] \int_{\beta_{min}}^{\infty} \frac{f(v)}{v} dv$$

Kamionkowski & Kouhiappas (2008)

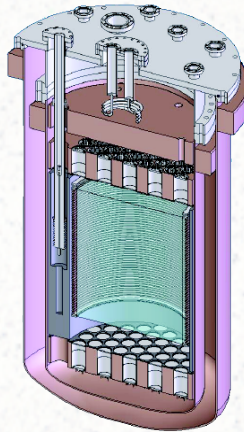

Kamionkowski, Kouhiappas & MK (2010)
(see also Vogelsberger et al. 2009)

4) Substructure And Direct Detection

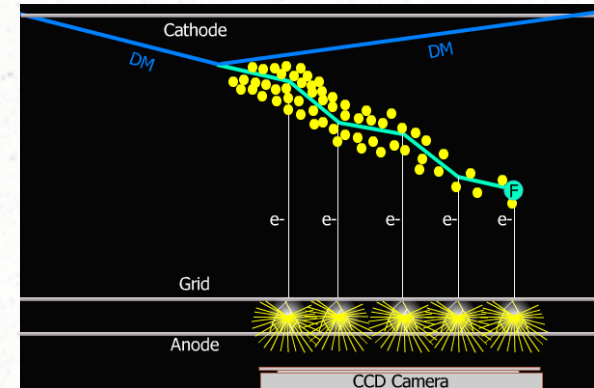

Cryogenic phonon detection
(e.g. CDMS)

Liquid Xenon scintillation
detectors (e.g. Xenon100, LUX)

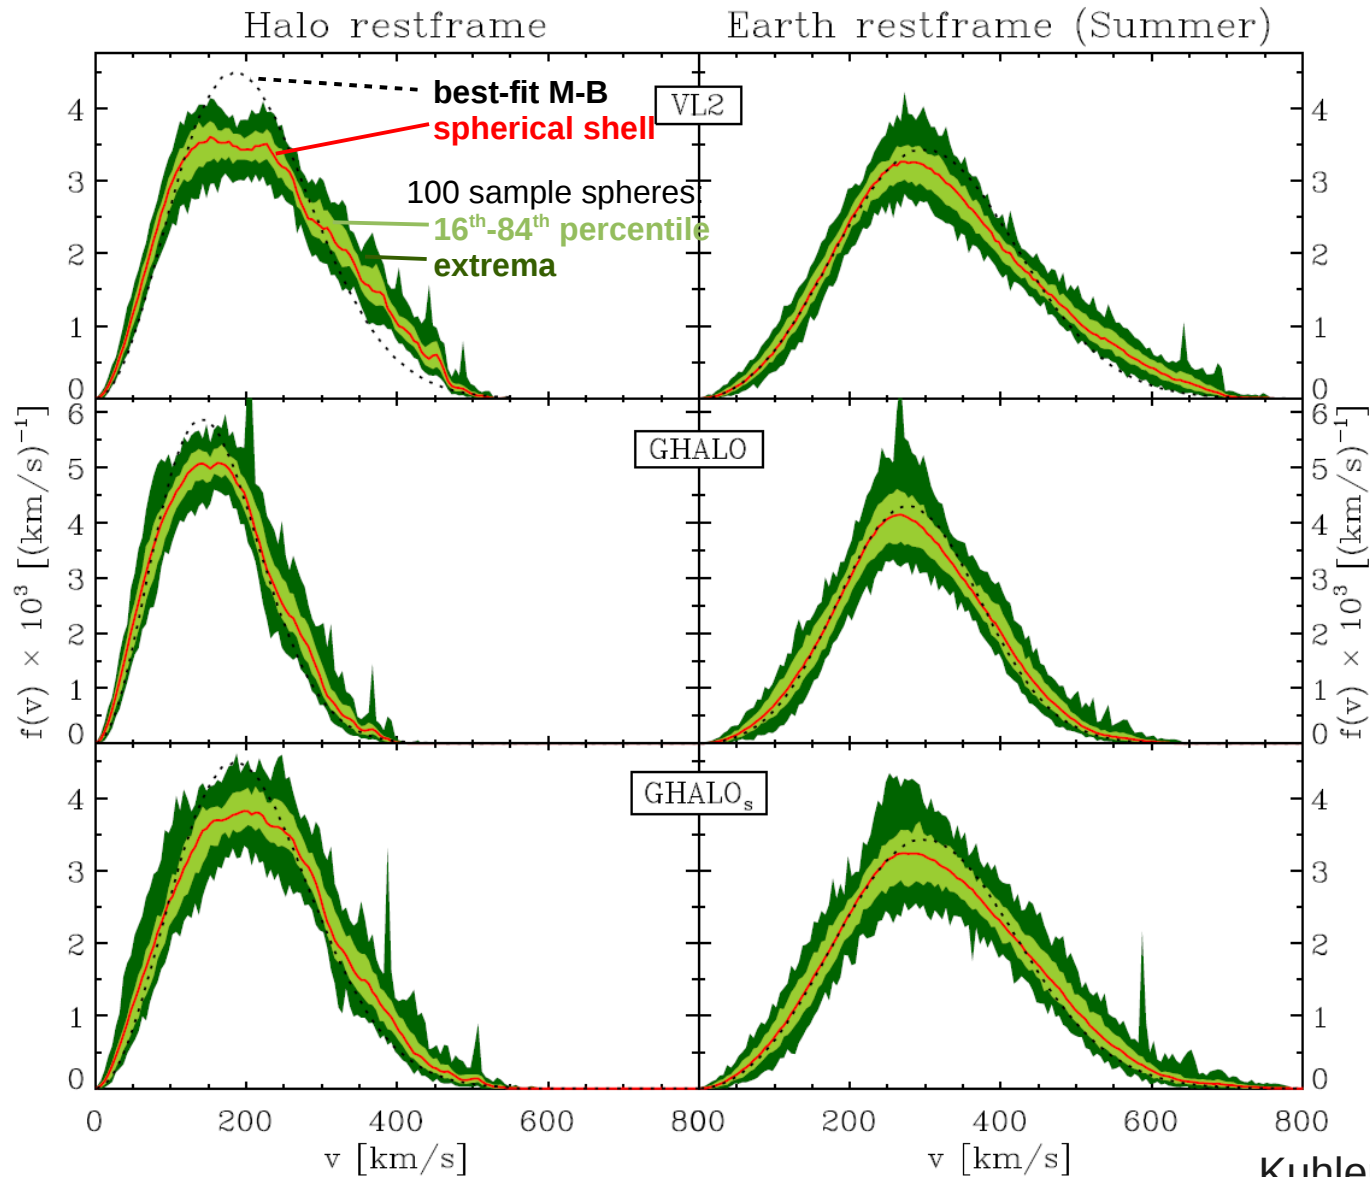

Directionally sensitive
(e.g. DRIFT, DMTPC)

$$\frac{dR}{dE_R} = N_T M_N \frac{\rho_\chi \sigma_n}{2m_\chi \mu_{ne}^2} \frac{(f_p Z + f_n (A - Z))^2}{f_n^2} F^2[E_R] \boxed{\int_{\beta_{min}}^{\infty} \frac{f(v)}{v} dv}$$

Velocity Space Substructure

Kuhlen et al. (2010)

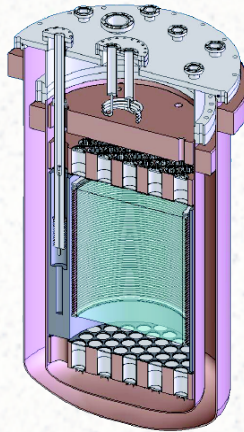

See also: Hansen et al. (2005), Vogelsberger et al. (2009)

4) Substructure And Direct Detection

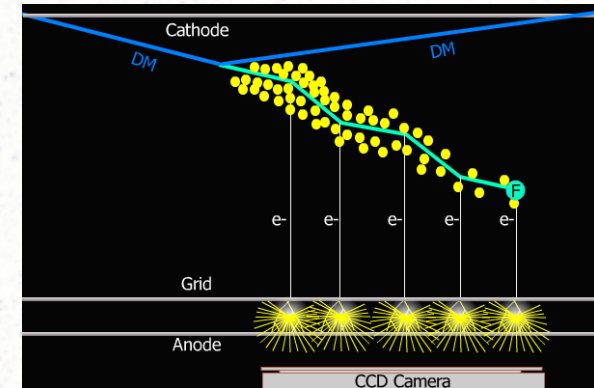

Cryogenic phonon detection
(e.g. CDMS)

Liquid Xenon scintillation
detectors (e.g. Xenon100, LUX)

Directionally sensitive
(e.g. DRIFT, DMTPC)

$$\frac{dR}{dE_R} = N_T M_N \frac{\rho_\chi \sigma_n}{2m_\chi \mu_{ne}^2} \frac{(f_p Z + f_n (A - Z))^2}{f_n^2} F^2[E_R] \int_{\beta_{\min}}^{\infty} \frac{f(v)}{v} dv$$

$f(v)$ is not Maxwellian!

Substructures can be important if β_{\min} is large.

$$\beta_{\min} = \sqrt{\frac{1}{2m_N E_R}} \left(\frac{m_N E_R}{\mu} + \delta \right)$$

- Inelastic DM ($\delta > 0$)
- Light DM ($M_\chi < 10 \text{ GeV}$)
- Directionally sensitive experiments often require high E_{recoil} , large β_{\min} .

4) Substructure And Direct Detection

Dark Matter Direct Detection...

We provide tables for the VL2, GHALO, and GHALO_s simulations. (See the paper and references therein for details on the simulations.) Additionally we provide tables for a case where we scaled the velocities of the particles to give $v_0=220$ km/s, where v_0 is the peak of halo rest frame $f(v)$ (i.e. the most probable speed). The velocity scaling factor is $f_v = 1.1875$ for VL2 and GHALO_s and 1.5556 for GHALO. An escape velocity cutoff of $v_{\text{esc}}=550$ km/s was applied. Note that we *did not use* these scaled distributions in our analysis, because we found that a lot of the interesting structure was pushed to beyond the escape velocity.

For each simulation, we provide one table for the spherical shell average (all particles with $8 \text{ kpc} < r < 9 \text{ kpc}$), a tarball containing tables for all 100 sample spheres, and a smaller tarball containing 10 DAMA-favorable sample spheres (i.e. spheres lying in the lower left corner of Fig.8).

4) Substructure And Direct Detection

McCabe (2010) made use of these tables to evaluate the dependence of exclusion limits from CDMS-II(Si), CDMS-II(Ge), CRESST-II, XENON10 on the $f(v)$ variation from the VL2/GHALO simulations.

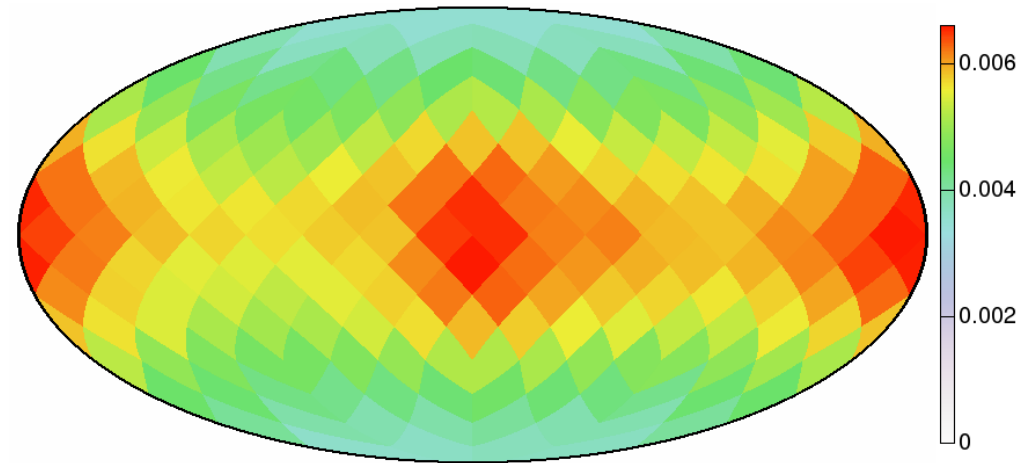

Velocity Direction in Halo Rest Frame

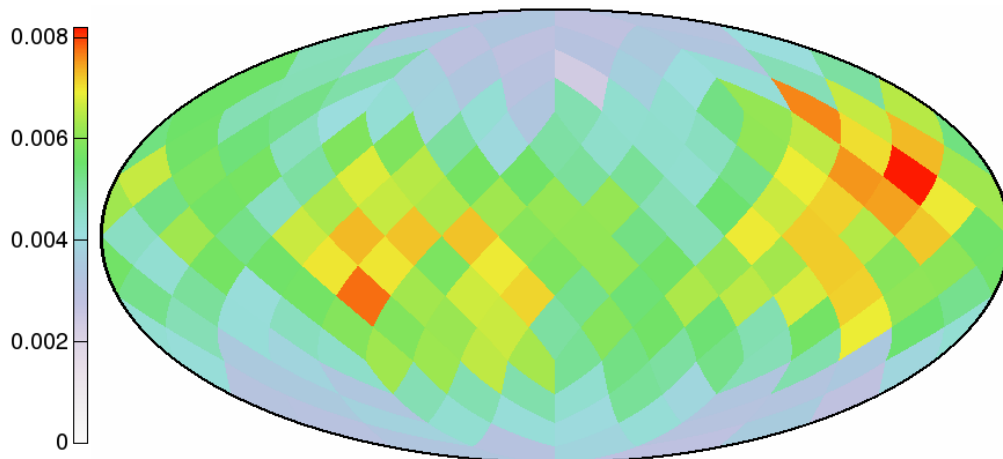

Maxwell-Boltzmann (isotropic)

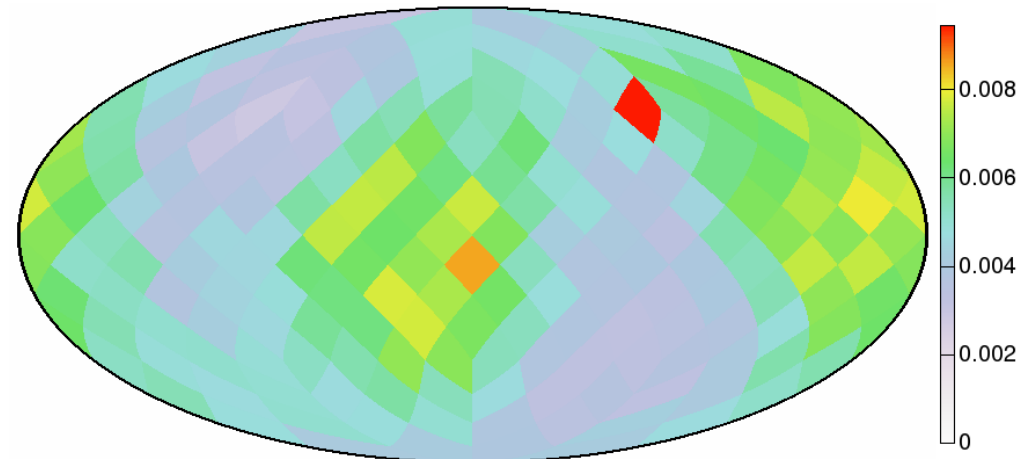

Spherical Shell ($8 \text{ kpc} < R < 9 \text{ kpc}$)

Sample Sphere #001

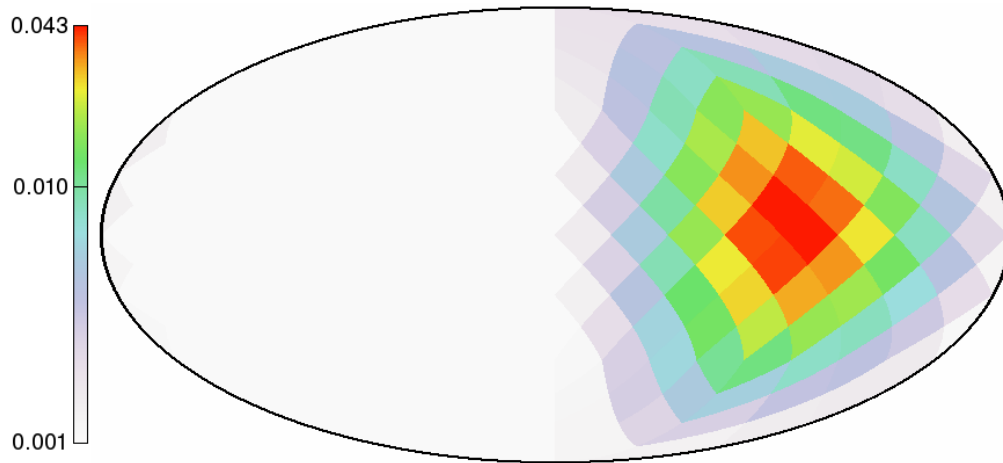

Sample Sphere #004 (containing a subhalo)

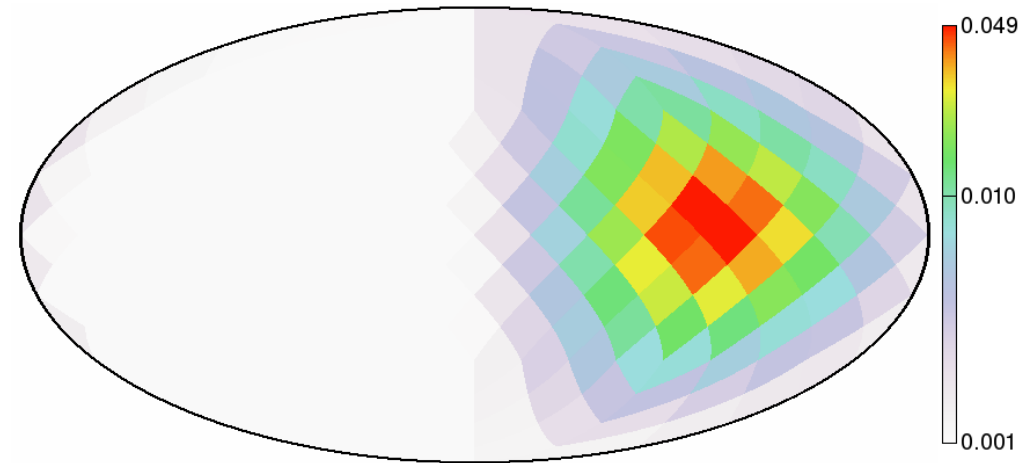

... in Earth Rest Frame $v_{\min} = 0$ km/s

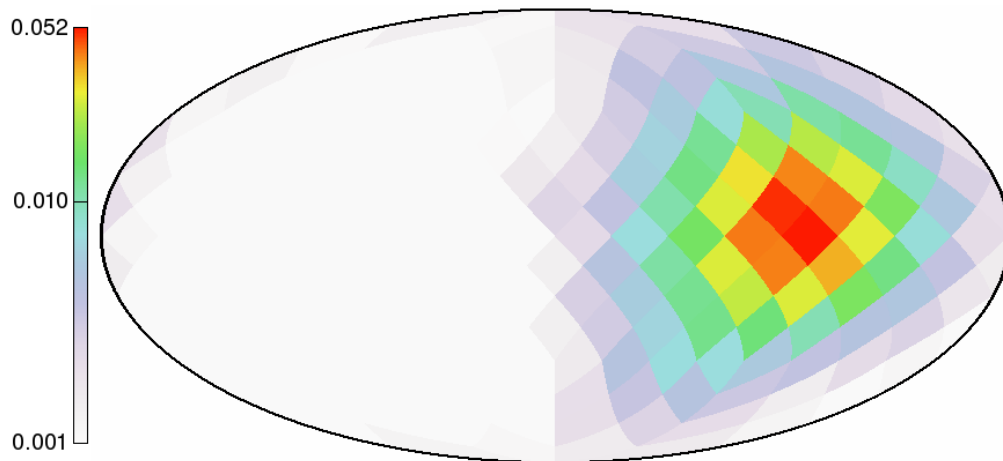

Maxwell-Boltzmann (isotropic)

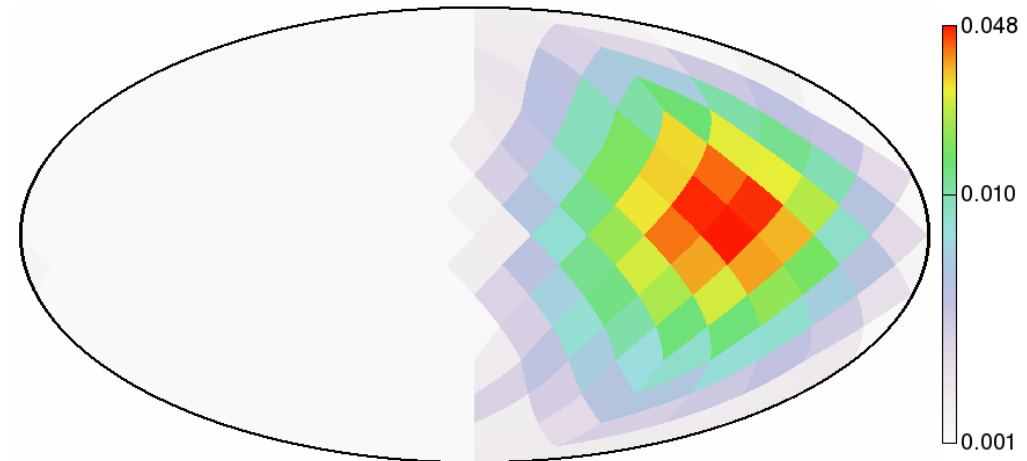

Spherical Shell (8 kpc < R < 9 kpc)

Sample Sphere #001

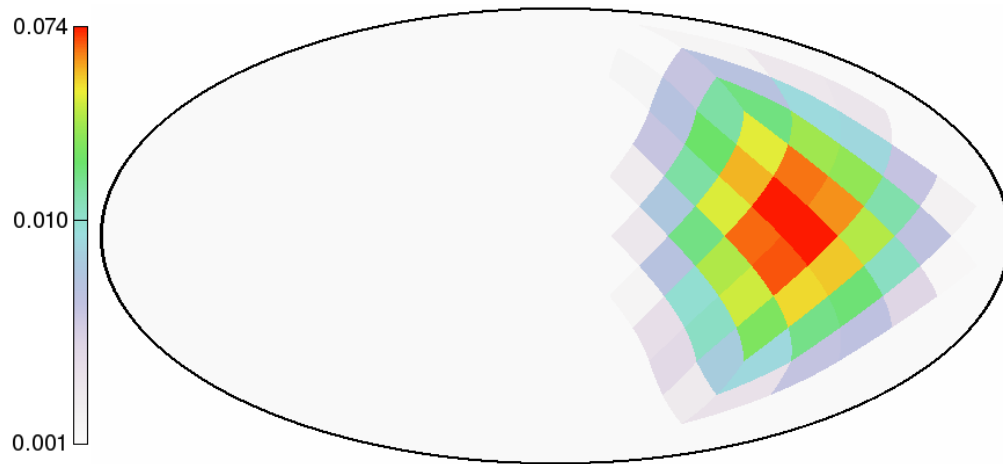

Sample Sphere #004 (containing a subhalo)

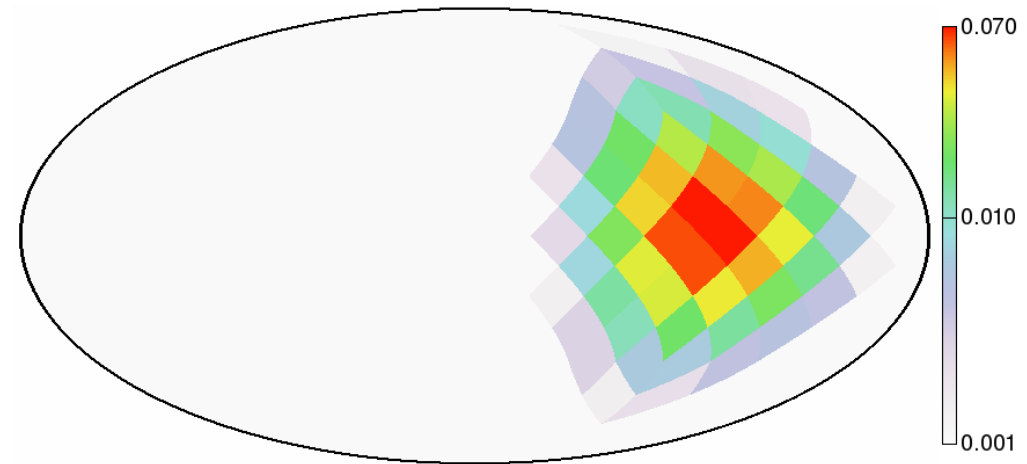

... in Earth Rest Frame $v_{\min} = 500$ km/s

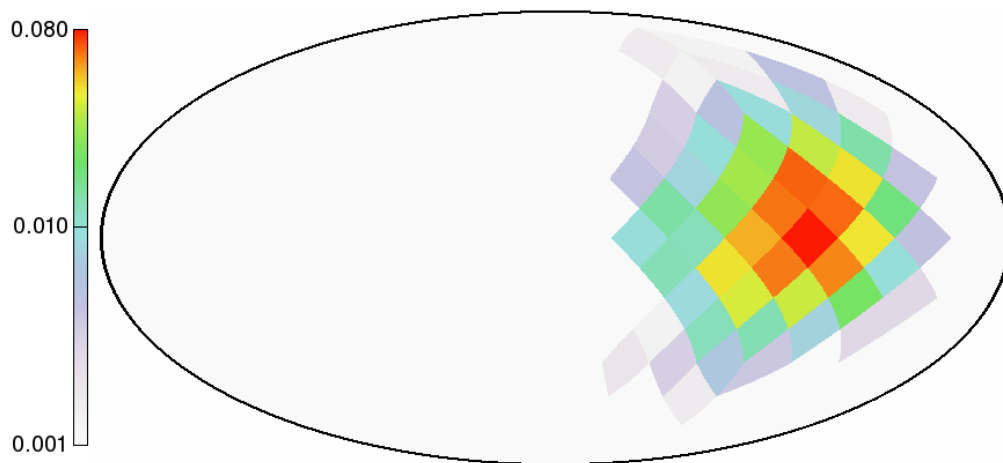

Maxwell-Boltzmann (isotropic)

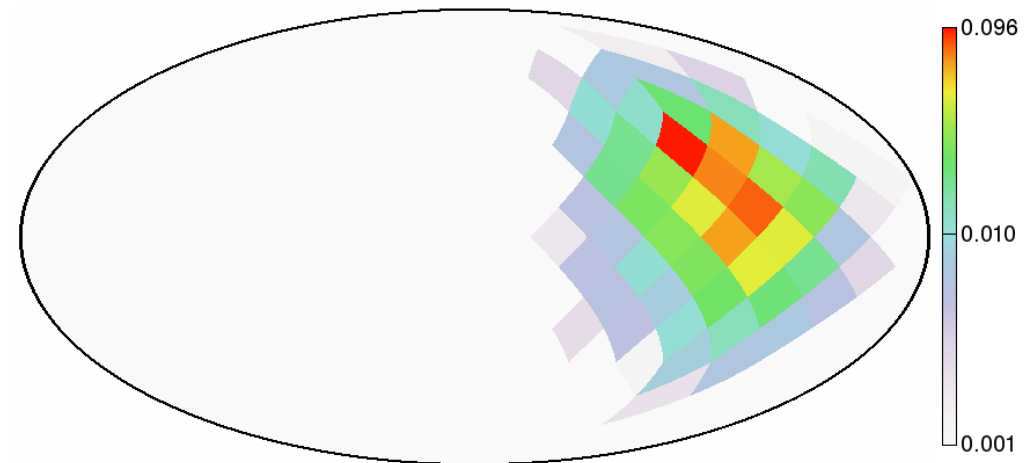

Spherical Shell (8 kpc < R < 9 kpc)

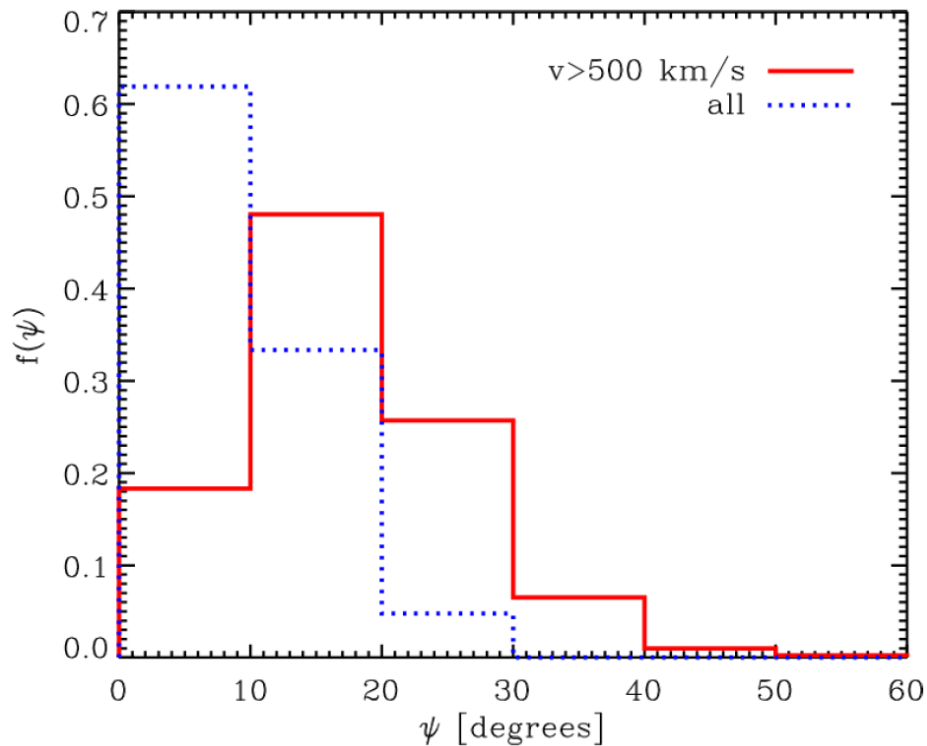

Sample Sphere #001

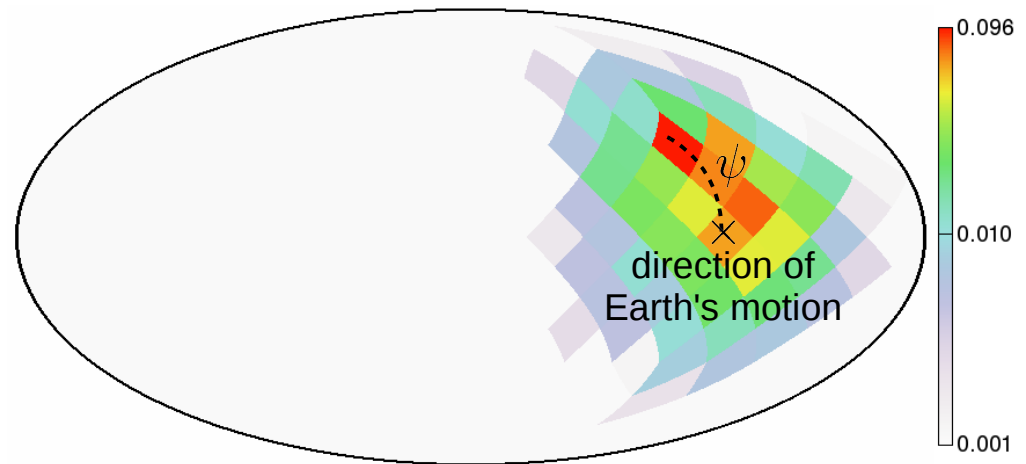

Sample Sphere #004 (containing a subhalo)

... in Earth Rest Frame $v_{\min} = 500$ km/s

Sample Sphere #004 (containing a subhalo)

At $v_{\min} = 500$ km/s the hotspot is more than 10° away from the direction of Earth's motion in $\sim 80\%$ of all cases!

Conclusions

- The number of subhalos resolved in the to-date largest simulations (Via Lactea II, GHALO, Aquarius) is ever increasing: >300,000 at latest count. Also lots of velocity substructure from subhalos and tidal streams.
- Once properly scaled, the Via Lactea, GHALO, and Aquarius simulations give consistent results.
- Simulations predict that Fermi should discover a handful of subhalos over its lifetime if the DM mass is <100 GeV and it annihilates through $b\bar{b}$. So far only limits.
- The annihilation boost factor from substructure depends on radius: at the GC or at the Sun it's not likely to be important.
- The total luminosity boost factor critically depends on the extrapolation of the subhalo concentration-mass relation.
- Velocity substructure in the DM distribution function might noticeably affect DM direct detection experiments, especially for DM models or experimental setups that are sensitive to high velocity DM particles: e.g. inelastic DM, light DM, directionally sensitive experiments.
